

# Lecture 11

# Fluorescence

by phytoplankton pigments and CDOM

Collin Roesler

23 July 2021

# Take Home Message

- Fluorescence is the property of a molecule to re-emit absorbed light energy at a longer wavelength (lower energy)
- Only certain molecules can fluoresce (e.g., chlorophyll a, some organic molecules), unique fingerprint
- Easy to measure, difficult to interpret (conservation of misery)
  - CDOM – complex composition
  - Chl – proxy for biomass, carbon, photosynthesis

# Fluorescence

- What is it
- Who does it
- Physics of fluorescence
- Fluorescence proxies
  - *In vitro*
  - *In vivo*
  - *In situ*
- Calibration/Validation
- Given sources of variability, what can we learn?

# *In vitro* chlorophyll fluorescence

- Extract appears green under ambient light
- When exposed to 440 nm light, appears red

# *In vivo* chlorophyll fluorescence

Light micrograph

epifluorescent microscopy

# Fluorescence

- What is it
- Who does it
- Physics of fluorescence
- Fluorescence proxies
  - *In vitro* – signal from chlorophyll in solvent extract
  - *In vivo* – signal from a living cell
  - *In situ* – bulk signal from the environment
- Validation
- Given sources of variability, what can we learn?

# Review of electronic and vibrational states for Chlorophyll (Jablonski diagram)

- Sketch the electronic energy levels for the two absorption peaks for Chlorophyll a
- Use color-coded arrows to represent absorption from the ground state to each electronic state
- Draw the associated spectrum

# Review of electronic and vibrational states for Chlorophyll (Jablonski diagram)

- Sketch the electronic energy levels for the two absorption peaks for Chlorophyll a
- Use color-coded arrows to represent absorption from the ground state to each electronic state
- Draw the associated spectrum

# Review of electronic and vibrational states for Chlorophyll (Jablonski diagram)

- What happens to the absorbed energy?
- absorbed **blue** light is excess energy for photosynthesis, during energy transfer, the excess is lost as heat  $\rightarrow$  from  $S_2$  to  $S_1$
- What about the energy from  $S_1$ ?
- Fluorescence emission, draw arrow to represent it on energy diagram and spectrum

# Review of electronic and vibrational states for Chlorophyll (Jablonski diagram)

- Add 3 vibrational levels for each electronic state
- Add associated absorption to vibrational energy levels, spectrum
- Heat loss from vibrational levels to lowest level of electronic state
- Heat loss from  $S_2$  to  $S_1$

# Review of electronic and vibrational states for Chlorophyll (Jablonski diagram)

- Add 3 vibrational levels for each electronic state
- Add associated absorption to vibrational energy levels, spectrum
- Heat loss from vibrational levels to lowest level of electronic state
- Heat loss from S<sub>2</sub> to S<sub>1</sub>

# Review of electronic and vibrational states for Chlorophyll (Jablonski diagram)

- Fluorescence from  $S_1$  ground state to  $S_0$  vibrational levels
- Add fluorescence to spectrum

# Review of electronic and vibrational states for Chlorophyll (Jablonski diagram)

- Fluorescence from  $S_1$  ground state to  $S_0$  vibrational levels
- Add fluorescence to spectrum

# Review of electronic and vibrational states for Chlorophyll (Jablonski diagram)

- Probabilities of occurrence in each vibrational level will determine relative absorption and fluorescence magnitudes
- Comparable for rotational levels

# Measuring fluorescence

- **Fluorescence Excitation Spectrum**

- Monitor fluorescence signal at some emission wavelength (e.g., 695 nm)
- Excite the sample with light along the spectrum
- Plot the magnitude of fluorescence associated with each excitation wavelength
- Ensure or correct for constant excitation energy across spectrum

- **Fluorescence Emission Spectrum**

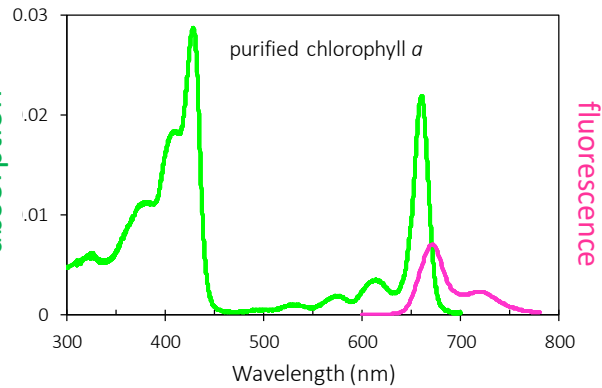

- Excite fluorescence at some excitation wavelength (e.g., 420 nm)
- scan the emission signal in response to excitation along the emission waveband
- Ensure uniform detection response across emission

- **Single Ex/Em (e.g., ECO sensor)**

- Excite at one wavelength (e.g., 420 nm)
- Measure emission at one wavelength (e.g., 695 nm)
- Calibrate to known chlorophyll concentration

# Fluorescence excitation and emission

## Chlorophyll

Data from Du et al., 1988.  
Photochem Photobio, 68: 141-142

## Phycoerythrin

<http://aatbioquest.blogspot.com/2014/07/rpe-r-phycoerythrin-and-its-tandems.html>

## CDOM

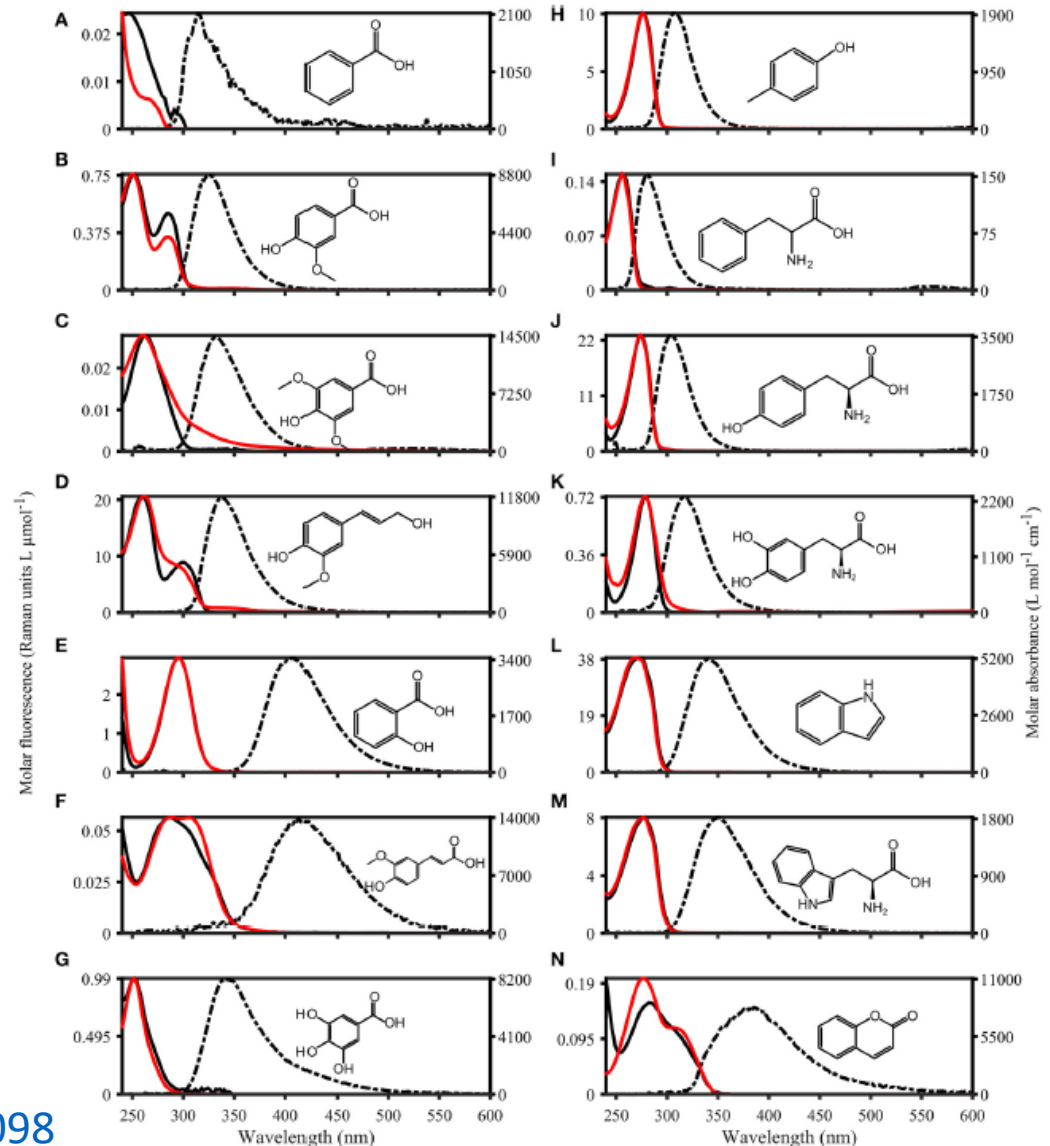

Zhao et al. 2017. Nature 8: 15284

# CDOM fluorescence

- Many fluorescing compounds
- Range of absorption, fluorescence spectra
- very complicated
- Molar absorption (red); Fluorescence (black dash)
- Longer excitation → longer emission

# Sensitivity of FDOM to environmental parameters

- Absorption and scattering
- Temperature

$$\text{FDOM}_{\text{corr}} = \text{FDOM}_{\text{raw}} + \rho(T_{\text{meas}} - 25) / r_p(\text{FNU}) \propto r_d(A_{254})$$

— FDOM raw  
— FDOM Corr<sub>temp</sub>  
— FDOM Corr<sub>temp+color</sub>  
— FDOM Corr<sub>temp+color+turb</sub>

# Fluorescence

- What is it
- Who does it
- Physics of fluorescence
- Fluorescence Proxies
  - In vitro (in a test tube, extract)
  - In vivo (in the cell)
  - In situ (in location, ocean)
- Calibration/Validation
- Given sources of variability, what can we learn?

# Fluorescence as proxies

- Chlorophyll fluorescence as proxy for
  - Chlorophyll concentration
  - *Phytoplankton* biomass
  - photosynthesis
- Phycoerythrin fluorescence as proxy for
  - Phycoerythrin concentration
  - *Cyanobacterial* biomass
- CDOM fluorescence as proxy for
  - “CDOM” concentration or absorption
  - Dissolved organic carbon concentration (DOC)

# Fluorescence Signal

Efficiency factor not radiant power

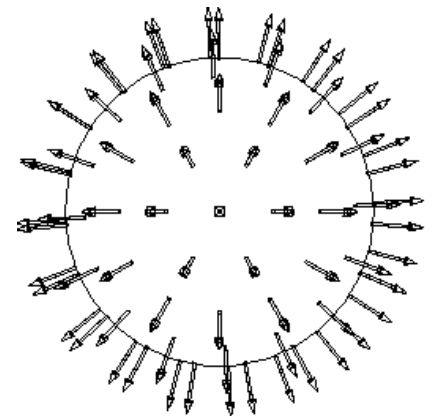

- $F_{chl}(\lambda_2) = E(\lambda_1) \times a_{chl}(\lambda_1) \times \Phi_f(\lambda_1, \lambda_2)$ 
  - Available light (spectral),  $E(\lambda_1)$  ( $\frac{\mu\text{mol quanta}}{\text{m}^2\text{s}}$ )
  - Chl absorption coefficient (spectral),  $a_{chl}(\lambda_1)$  ( $\text{m}^{-1}$ )
  - Fluorescence efficiency (quantum efficiency),  $\Phi_f$  ( $\frac{\text{quanta fluoresced}(\lambda_2)}{\text{quanta absorbed}(\lambda_1)}$ )
  - Units on  $F$ ?
    - $\left(\frac{\mu\text{mol quanta}}{\text{m}^2\text{s}}\right) \times (\text{m}^{-1}) \times \left(\frac{\text{quanta fluoresced}(\lambda_2)}{\text{quanta absorbed}(\lambda_1)}\right)$
    - $= \left(\frac{\text{quanta fluoresced}(\lambda_2)}{\text{m}^3\text{s}}\right)$

$E(\lambda_1)$  (hold  $a_{chl}$ ,  $\Phi$  constant)

$a_{chl}(\lambda_1)$  (hold  $E$ ,  $\Phi$  constant)

# *In vitro* Fluorescence, chlorophyll proxy

- $F_{chl}(\lambda_2) = E(\lambda_1) \times a_{chl}(\lambda_1) \times \Phi_f(\lambda_1, \lambda_2)$
- $F_{chl} = E \times a_{chl}^* \times [Chl] \times \Phi_f$
- Chl molecules in solution,  $[Chl]$
- Constant mass-specific absorption,  $a_{chl}^* (m^2 mg^{-1})$
- Constant quantum yield,  $\Phi_f$  (no physiological pathways)
- Maintain constant  $E$
- Fluorometers relative units, ( $dc$  or volts)
- Calibrate with  $Chl$  standard solution
- *We will do this in lab today*

# *In vivo* Fluorescence Physiology

- Phytoplankton contain multiple chloroplasts, membrane-bound organelles
- The chloroplasts contain structures called grana, which are stacks of thylakoid membranes
- The thylakoid membranes have embedded pigment-protein complexes that contain light harvesting complexes of pigments and reaction centers, these are called photosystems and are the site of photosynthesis
- Light harvesting chlorophyll molecules are embedded in thylakoid membranes via the phytol tail

# *In vivo* Fluorescence Physiology

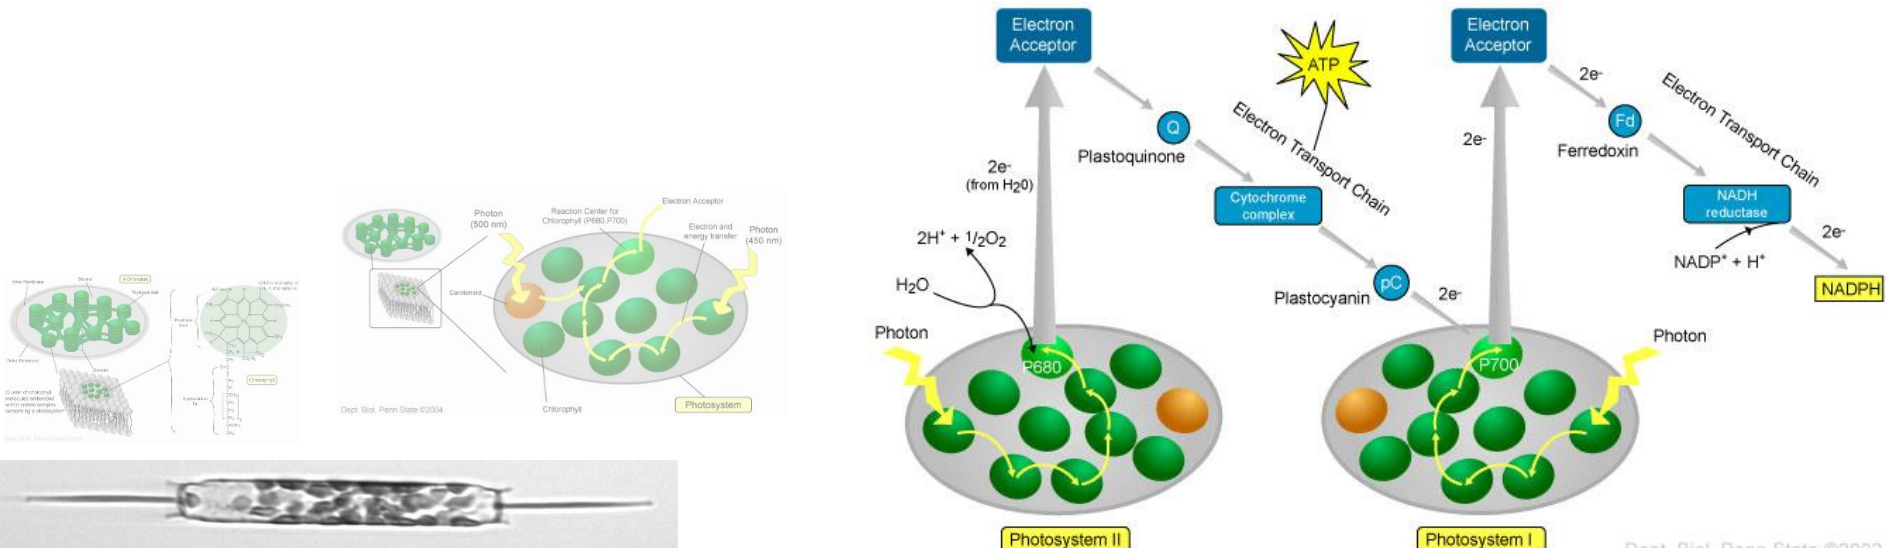

- The chlorophyll *a* molecules responsible for absorbing blue light are called the antenna chlorophylls
- Carotenoids and other chlorophylls (b and c) absorb longer wavelengths towards the green range (and red)
- Photosynthetic pigments transfer energy to the reaction center chlorophyll molecules, the transfer between adjacent molecules is an efficient radiationless and lossless dipole-dipole resonance that results from overlapping absorption spectra

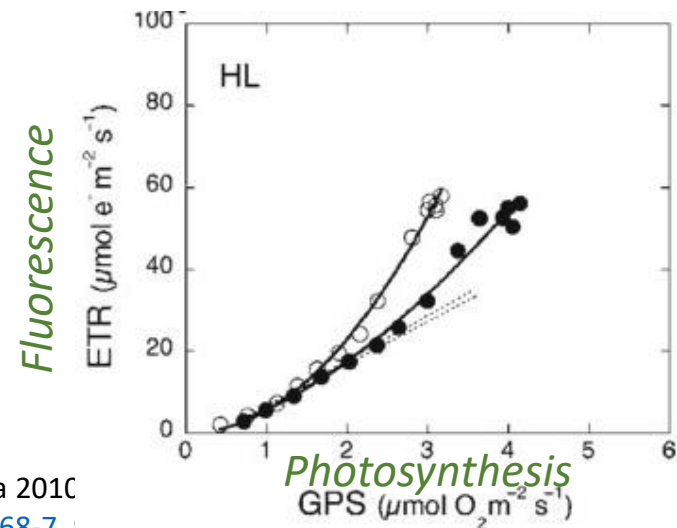

# *In vivo* Fluorescence Physiology

- Ultimately the absorbed energy is transferred to chlorophylls in the reaction centers at a wavelength equal to either 680 nm or 700 nm for the second and first photosystems, respectively
- Once the reaction center chlorophylls are in the excited state (higher electronic levels), they pass their electrons to acceptor molecules along the electron transport chains
- Water is split to replace the electron in the photosystem 2 reaction center, and oxygen is released
- The result is the formation of a reductant (NADPH) and ATP which will drive carbon fixation in the dark reactions (Calvin Cycle)

# *In vivo* Fluorescence Physiology

- What does this have to do with fluorescence
- It is the chlorophyll molecules in the light harvesting complex that fluorescence when they cannot transfer their energy
- Initially, the more light that is absorbed, the more photosynthesis occurs *and* the more fluorescence, they vary linearly with irradiance
- As the photosynthetic rate reaches its maximal rate, excess absorbed energy is dissipated via fluorescence (and other processes), so the ratio between fluorescence and photosynthesis increases → photoinhibition of photosynthesis
- Eventually, fluorescence is also photoinhibited → non-photochemical quenching

# *In vivo* Fluorescence Proxies

- To first order, fluorescence is a proxy for chlorophyll, the more phytoplankton, the more chlorophyll, the more fluorescence
- Under limiting light levels, fluorescence is a proxy for photosynthesis (via chlorophyll and absorption)
- Under increasing light levels, photosynthesis reaches maximal rates while fluorescence can continue to increase
- Under saturating light levels, fluorescence is not a proxy for chlorophyll, but may again become a proxy for photosynthesis as both are quenched

# *In vivo* Fluorescence, chlorophyll proxy

- $F_{chl}(\lambda_2) = E(\lambda_1) \times a_{chl}(\lambda_1) \times \Phi_f(\lambda_1, \lambda_2)$
- $F_{chl} = E \times a_{phyt}^*(\lambda) \times [Chl] \times \Phi_f$
- Chl molecules bound to proteins, membranes
  - other physiological pathways
  - variations in quantum yield ( $\sim \ll 1-3\%$ ),  $\Phi_f$
  - Variations in mass-specific phytoplankton absorption,  $a_{phyt}^*(\lambda)$
- maintain constant  $E$
- fluorometers relative units
- Calibrate with extracted Chl samples
- How bad can it be?
- *We will do this in lab today*

$F_{chl}$   
(dc)

$[Chl]_{ext}$

# How many have experienced this?

- Freshly calibrated fluorometer
- Paired *in situ* calibrated fluorescence and extracted chlorophyll concentration for validation
- ugh

- Mass Bay, 1069 paired samples

# Calibration – from volts to $\text{mg}/\text{m}^3$

- Standards
- “solid standards” trace signal, not convert volts to [Chl]
- *In vitro* chlorophyll
  - Purified chlorophyll *a*
  - Solvent effects (wavelength shift and packaging)
  - LED excitation mismatch
    - Many sensors 470 nm excitation
    - Chlorophyll in extract doesn't absorb at 470 nm
    - 470 nm absorbed by accessory pigments, transferred to chlorophyll *a*, then fluoresced

# Calibration – from volts to mg/m<sup>3</sup>

- Standards
- *In vivo* chlorophyll *a* (living culture)
  - *Traceable?*
    - Easy to culture
    - Ubiquitous
    - Robust optical properties
    - *Thalassiosira pseudonana*
    - Growth conditions
      - Replete but not inhibiting light 250  $\mu\text{E}/\text{m}^2/\text{s}$
      - 24h to discourage diel cycles/phases
      - Replete nutrients
      - Exponential growth
    - Database of chlorophyll, HPLC pigments, absorption, size, POC

# Lab Today: Calibration Standard Curve

- phytoplankton dilution series
- Measure  $F_{chl}$  of each dilution
  - Best in dark large volume casket
  - We will do beakers in dark room  $F(dc)$
- Measure extracted  $[Chl]$  of each dilution

live culture

Culture dilution  $\rightarrow [Chl]$

# Calibration Standard Curve

- Calculate linear regression statistics (type II, std dev)
- Calibration slope,  
 $m = slope = \frac{F_{meas}}{[Chl]} \left( \frac{dc}{mg\ m^{-3}} \right)$   
Fluorescence yield
- Intercept,  $b(dc)$ , is medium blank (not the dark)
- Measure taped dark,  
 $F_{dark}(dc)$

Equation to estimate Chl from measured fluorescence

$$Chl(mg\ m^{-3}) = \frac{F_{meas} - F_{dark}}{m}$$

# Critical considerations for understanding *Sensor Uncertainty*

Characterizing your sensors is critical because you want the observations you make today to be:

- quantitative (i.e., mg chl/m<sup>3</sup>)
  - traceable (quantitatively related) to those you make tomorrow
  - traceable to those you make with your other sensor
  - traceable to those your colleagues make
- climate quality data records

# Fluorescence

- What is it
- Who does it
- Physics of fluorescence
- Fluorescence proxies (*physiology* of fluorescence)
  - *In vitro*
  - *In vivo*
  - *In situ*
- Calibration/Validation
- Given sources of variability, what can we learn?

# There is so much more to say but that can wait until another time

- Multi-channel fluorescence as a tool for discerning phytoplankton groups
- Considerations in interpreting the fluorescence from different platforms
  - Profiling from a boat
  - Moored
  - Profiling on gliders and floats
- Non-photochemical quenching
