

## **Module 9**

# **Advanced Data Processing**

## Overview

This section of the course is the final topic in profiling. Some of it is fine tuning of your data to remove small artifacts of frequency counting, plumbing, and sensor physics. We will also discuss the removal of the fairly gross effects of ship heave. Understanding these topics will help explain most of the peculiar things that you might observe in your data if you look closely.

Finally, we will talk about bin averaging your final data, and batch processing of large numbers of files.

When we finish this module you should be able to:

- Align your conductivity and temperature data relative to pressure.
- Filter your conductivity data so it matches the time response of your temperature data in an SBE *19plus*.
- Align your dissolved oxygen data relative to pressure.
- Remove the effects of conductivity cell thermal mass from your data.
- Remove data artifacts caused by ship heave.
- Bin Average to reduce your data set, producing data at even pressure or depth values.
- Batch process large number of files.

## Errors in CTD Data

### Why worry about Absolute Accuracy in Sensors?

- In oceanography, we measure physical quantities to calculate many parameters necessary to analyze the ocean
  - Thermodynamic properties are needed in ocean/climate models
- Calculated parameters (salinity) rely on accurate measurement of temperature, conductivity, and pressure
- Small errors in original measurements can lead to large errors in calculated parameters
  - These small errors can lead to big errors in data analysis and interpretations

## Errors in CTD Data (*continued*)

### Types of Errors in CTD Data

- Dynamic Errors
  - Errors incurred while sampling on moving platforms or on moorings where conditions are changing rapidly
  - Response time of sensors
- Static Errors (*discussed already*)
  - Initial and post-deployment calibration accuracy
  - Reported on calibration and specification sheets
- Sensor Drift Characteristics (*discussed already*)
  - Sometimes reported on specification sheet
  - Does not address fouling drift

In this module, we discuss how to process and improve data for Dynamic Errors.

---

## Dynamic Errors in Temperature

### Dynamic Errors in Temperature

- Response time of sensor to changing condition
- Temperature response time largely determined by physical size and construction.
  - Response time for profiling CTDs
    - 0.070 sec (SBE 9-11*plus* and 25*plus*)
    - 0.5 sec (SBE 19*plus*)
  - Response time for moored CTDs 0.5 sec
- Corrected in data processing

## Dynamic Errors in Conductivity

### Dynamic Errors in Conductivity

- Response time of sensor to changing temperature AND salinity
  - Depends on flow speed through cell
  - Depends on thermal mass of materials that make up sensor
- For both high and low accuracy (0.1 to 0.002 PSU), response time and thermal lag errors can be significant
- On free-flushed sensors where flow rates are always changing, these errors cannot be avoided or corrected
- **Only on flow-controlled CTDs can these errors be corrected for**

In these examples, the temperature and conductivity sensors are not sampling the same water parcel. This will lead to errors in computed salinity and density.

## Dynamic Errors in Salinity

**SBE** Dynamic Errors in Salinity:  
 1. Not Sampling Same Water Parcel

- T and C sensors measuring different parcels of water

*Example of Non-plumbed SBE sensors*

CTD Tilted

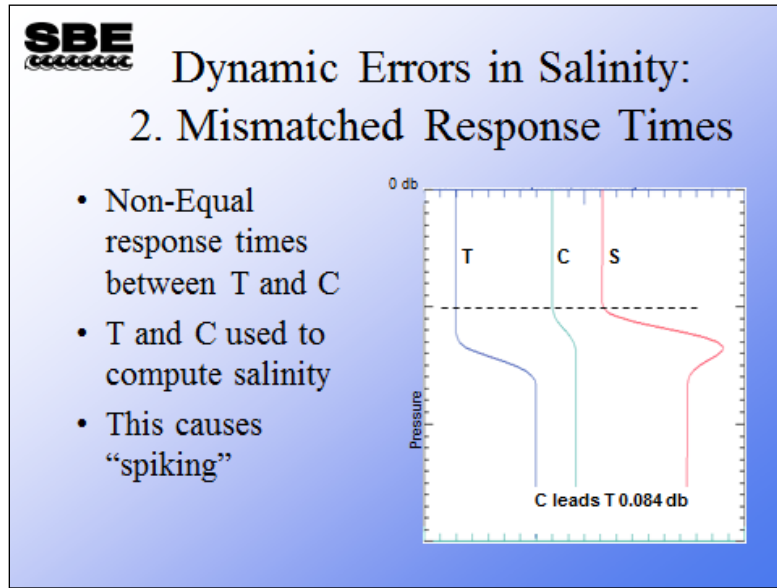

Physical Misalignment

Other Company's T and C sensors

COND

TEMP

## Dynamic Errors in Salinity (*continued*)

In this example, the conductivity sensor responds to a change faster than the temperature sensor. This causes the salinity to *spike* high of correct.

## Dynamic Errors in Salinity (*continued*)

**SBE** Dynamic Errors in Salinity:  
3. Temperature Error caused by  
Thermal Mass of Conductivity Cell

Conductivity measurement is very sensitive to thermal mass of the cell  
– 90% of the C signal is dependent on temperature

*Image of a cold cup that changes color after putting hot coffee into it*

*Time it takes to change the temperature to new value is the thermal mass lag*

All materials can be heated up, some more easily than others. For example, a cast iron pan will get hotter than an aluminum pan when heated for the same length of time. A ceramic cup full of hot tea can be comfortably held, but a metal cup full of hot tea would be too hot to hold.

Different materials have different capacities for heat. The amount of heat that any given amount of material can hold is either called that material's thermal capacity or its **thermal mass**. The lower its heat capacity, the less energy it needs to raise its temperature. If it has a high heat capacity, it can store a lot of energy at any given temperature.

Since sensors are made of thermally conductive materials, we should understand how the sensor body materials affect the thermal mass, hence the measurement.

## Dynamic Errors in Salinity (*continued*)

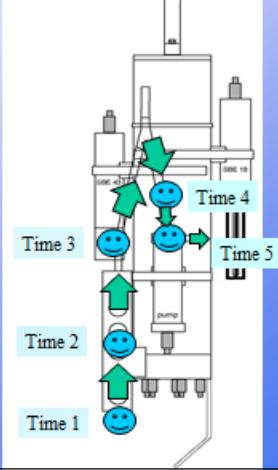

The error caused by ship motions, known as ship heave, comes from the instrument package disturbing the water that it is trying to sample. Because of this, there is no numerical solution for the problem. SBE Data Processing has an editor that will mark (flag) the offending data, so that it is not used in your final calculations. As winch technology improves, we can expect to see vessels equipped with motion compensation capability, which will greatly reduce this problem. Until that is available, you may want to profile a bit more quickly to reduce the effect of ship heave in rough water.

## Reducing Dynamic Errors

**SBE**  
Sea-Bird Solution to  
Reducing Dynamic Errors

1. Make measurements on the same water parcel at stations along a pump-controlled flow path
2. This allows us to post-process data to significantly reduce dynamic errors

The diagram illustrates a pump-controlled flow path for water sampling. It shows a vertical assembly with a pump at the bottom. Five blue smiley faces represent measurement stations at different points in the flow path, labeled Time 1 through Time 5. Green arrows indicate the direction of flow: from the pump up to Time 1, then down to Time 2, up to Time 3, down to Time 4, and finally up to Time 5. The flow path is controlled by a pump, ensuring that the same water parcel is measured at each station.

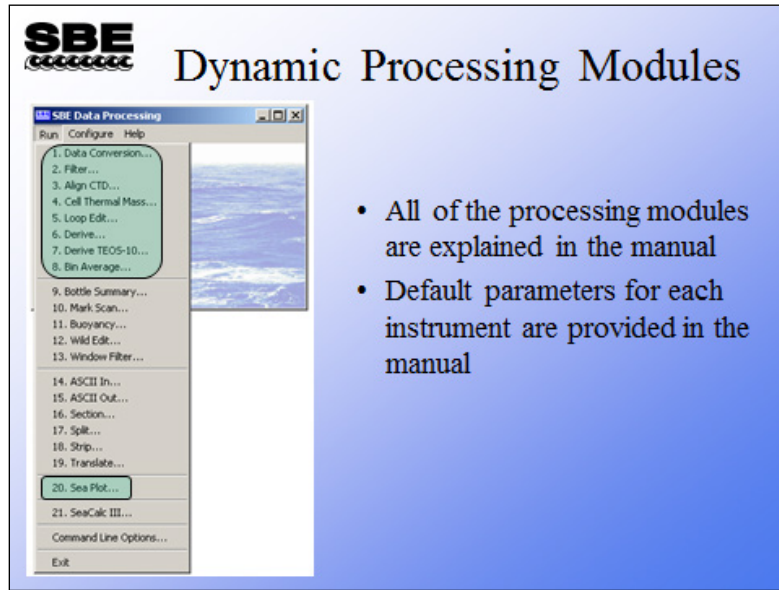

## Reducing Dynamic Errors (*continued*)

**SBE**  
*seawater*

### Flow Control

- Forces sensors to measure same water parcel, but at different times
- Can correct for differences in time each sensor takes its reading because we have constant flow (speed) and sample rate
- Provides constant response time for sensors that are flow dependent (conductivity and oxygen)
- Constant flow and sample rate allows for response time adjustments between sensors (similar to time of sample adjustment)
- Reduces thermal mass amplitude and lag PLUS allows us to correct for it
- Can separate alignment issues from ship heave
- By adjusting flow speed, we can better match response times of sensors (T and C) on SBE *9plus*
  - Lag is fixed and can be removed with high precision (SBE *19plus*, *19plus V2*, *25*, *25plus*)

## Data Processing Modules

The screenshot shows the 'SBE Data Processing' application window. The title bar reads 'SBE Data Processing' with standard window controls. Below the title bar is a menu bar with 'Run', 'Configure', and 'Help'. The main area is a list of 21 processing modules, numbered 1 through 21. Modules 1 through 8 are grouped in a light green box, and module 20 is highlighted with a darker green box. To the right of the list is a small preview window showing a blue-toned image of a landscape. The list of modules is as follows:

1. Data Conversion...
2. Filter...
3. Align CTD...
4. Cell Thermal Mass...
5. Loop Edit...
6. Derive...
7. Derive TEOS-10...
8. Bin Average...
9. Bottle Summary...
10. Mark Scan...
11. Buoyancy...
12. Wild Edt...
13. Window Filter...
14. ASCII In...
15. ASCII Out...
16. Section...
17. Split...
18. Strip...
19. Translate...
20. See Plot...
21. See Calc III...

At the bottom of the list are 'Command Line Options...' and 'Exit'.

- All of the processing modules are explained in the manual
- Default parameters for each instrument are provided in the manual

## Data Processing Modules (*continued*)

### Key SBE Data Processing Modules for Profiling CTDs

- **Data Conversion** converts data from hexadecimal to engineering units
- **Wild Edit** or **(Median) Filter** to remove outliers
- **Align CTD** coordinates measurements of T, C and P on same parcel of water
  - Other variables as well as needed
- **Filter** refines response time of sensors and smoothes digital noise in Pressure data
- **Loop Edit** (*Optional*) reduces ship heave effects by marking scans "badflag" if the scan fails the minimum velocity criteria set by the user
- **Cell Thermal Mass** corrects conductivity sensor thermal lag error for a given flow rate determined by pump speed or estimated based on descent rate
- **Derive** takes the newly aligned and corrected independent variables (T, C, P, Oxvolts) and computes the dependent variables (Salinity, Density, Oxygen Concentration)
- **Bin Average** statistically averages data blocks into bins that are evenly spaced or interpolated pressure, depth, scan count or time blocks
- **Split** separates up and down casts
- **ASCII In** transforms an ASCII Text file with columns of data into a SBE formatted .cnv (converted) file for processing and plotting in SBE software
- **ASCII Out** transforms a SBE formatted file and outputs a simple column file of data in text format...this can be used in Excel and other non-SBE programs

---

## Data Processing: Converting Independent Variables

### Converting Dependent Quantities vs. Raw Independent Quantities

- Salinity and Oxygen are computed quantities
  - They are what we call *Dependent Variables* as they rely on Independent Variables (T,C, P, OXVOLTS)
- For successful computation of Dependent Variables, inputs need to be accurately measured AND accurately coordinated on a point in space, and secondarily coordinated in time response
- If these Independent Variables are measured or coordinated incorrectly, this will have ripple effect in other computed quantities
  - density, buoyancy frequency, etc.

## Data Processing: Converting Independent Variables (continued)

**SBE**  
*seawater*

For Example:

How to get salinity with only 10% of signal

- Electrical measurement of conductivity
  - 90% of signal from temperature
  - 10% from salinity based on conducting ion content of seawater
- 1% error in Temperature causes 10% error in Salinity
- **Always compute Salinity AFTER we process Temperature, Conductivity, and Pressure**

## Activity: Convert Data

Explanation: We are preparing to operate on the data with an application that moves the T and C data streams relative to the pressure data stream. Calculation of parameters that are functions of T, C, and P is not useful at this stage, and it will complicate and confuse things to have them in the data set before we are ready for them. So, just convert the measured variables – pressure, temperature, and conductivity.

1. In SBE Data Processing, run *1. Data Conversion*:

A. File Setup tab –

- Input files C:/Data/Module9/AlignC/Faroe.dat and Faroe.con
- Output file Faroe.cnv

B. Data Setup tab -

- Downcast only
- Convert...

Pressure, Digiquartz

Temperature,2 [ITS-90] – ('2' indicates this is **secondary T** on an SBE 9*plus*)

Conductivity,2 [S/m] – ('2' indicates this is **secondary C** on an SBE 9*plus*)

C. Click *Start Process*.

---

If you have time, convert 19*plus* data (C:\Data\Module9\AlignC\SBE19plus\Miami.hex, using Miami.con). The 19*plus* has no secondary sensors.

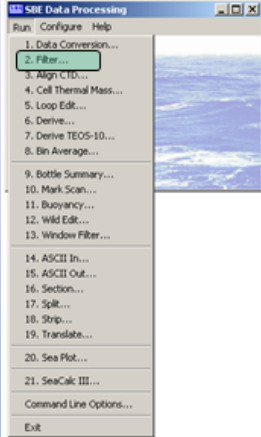

- Downcast only
- Convert...
  - Pressure, Strain Gauge -> db
  - Temperature -> ITS-90 -> deg C
  - Conductivity -> S/m
- Output file Miami.cnv

## Filtering Data

### Filtering Data for Matching TC Sensor Time Responses

- Conductivity cell has a time constant (Tau) that depends on pumping rate
  - Temperature response is not flow dependent
- SBE *9plus* pump and TC duct controls Tau of C to match Tau of T
  - No Filtering required
- SBE 25 and 25*plus* pump is slower than pump used with *9plus*
  - Filtering T and C optional for SBE 25
  - Filtering T and C recommended for SBE 25*plus*
- Tau for SBE 19*plus* and 19*plus* V2 T and C are not as well matched; require filtering of T and C

It is very desirable to match the time constants of the temperature and conductivity sensors. This improves salinity data in conditions of sharp gradients. The conductivity sensor has a time constant that depends on pumping rate; it can range from 10 millisecc at a fast pumping rate to very large if no water is moving through the cell.

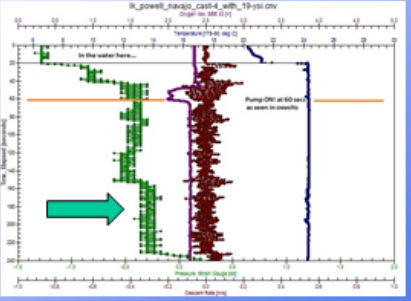

- For the *9plus* with a TC duct and standard plumbing, a pumping rate of 25 ml/s brings the conductivity sensor's time constant in line with the temperature sensor's time constant of ~70 ms.
- The SBE 25 and 25*plus* use the same sensors as the *9plus*, but these CTDs usually includes a slower pump (2000 rpm vs 3000 rpm). A small amount of filtering of temperature and conductivity is usually recommended.
- The 19*plus* and 19*plus* V2 temperature sensor has a much slower time constant than its conductivity sensor, as we saw in the first part of the course. Because of the way the filtering algorithm operates, the best match of temperature and conductivity is obtained by filtering both channels with a filter having the same time constant as the temperature channel.

## Filtering Data (*continued*)

**SBE**  
cccccccc

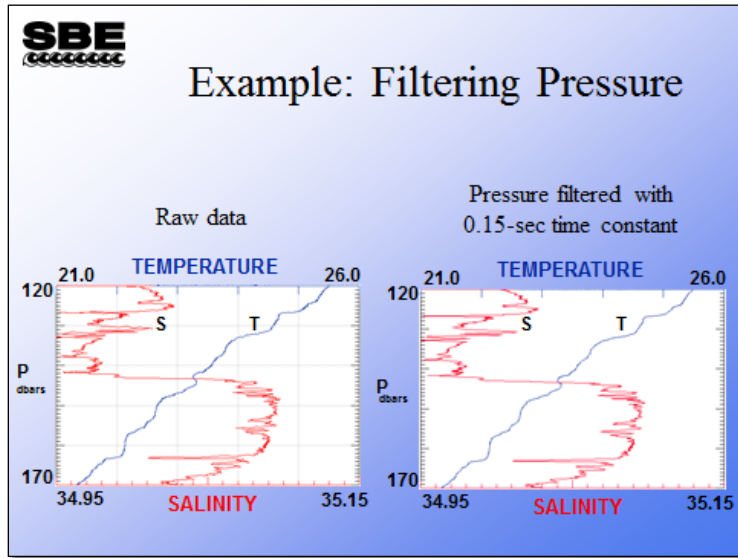

### Filtering Pressure to Remove Digital Noise

- Filtering pressure data removes digitization noise
- Filter pressure data if:
  - You are going to use *Loop Edit* to remove data artifacts, and/or
  - You are interested in fine scale in SBE 9plus

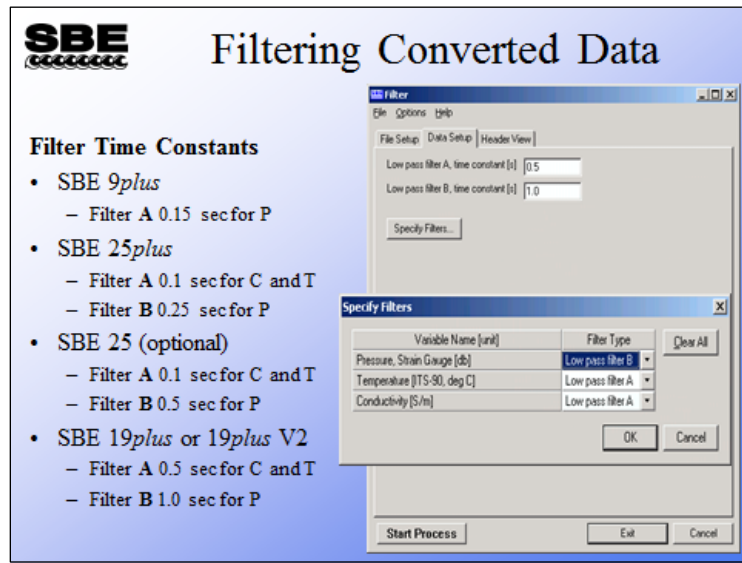

In measuring the pressure sensor signal, there is a digitization error that may be removed by filtering the signal with a low-pass filter. This has the effect of improving the resolution of the pressure signal by smoothing the digitization jitter.

## Filtering Data (*continued*)

The left plot shows some *dithering* in the data that is eliminated by filtering the pressure.

## Filtering Data (*continued*)

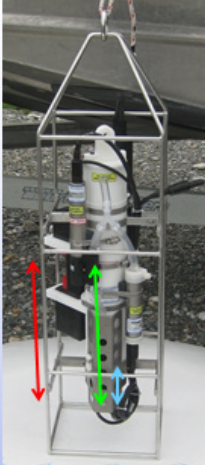

Filtering is done for two reasons:

- To match the time constants of the temperature and conductivity sensors.
- To smooth the pressure signal to minimize digitization noise in preparation for removing *loops* in the data with *Loop Edit*. When smoothing pressure, use a filter that is approximately four times the sample rate:
  - SBE *9plus* – samples at 24 Hz (0.04167 sec),  $4 \times 0.04167 \approx 0.15$  sec
  - SBE *25plus* – samples at 16 Hz (0.0625 sec),  $4 \times 0.0625 = 0.25$  sec
  - SBE 25 – samples at 8 Hz (0.125 sec),  $4 \times 0.125 = 0.5$  sec
  - SBE *19plus* or *19plus V2* – samples at 4 Hz (0.25 sec),  $4 \times 0.25 = 1$  sec

## Illustrating Sensor Alignment

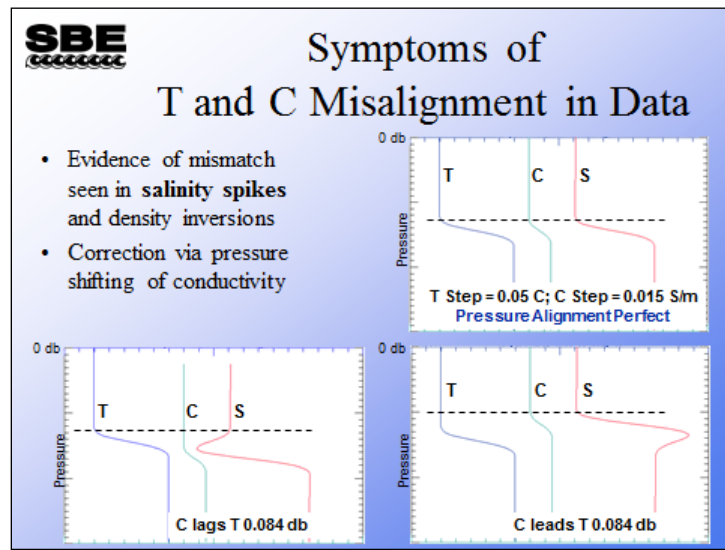

**SBE**  
*sevens*

### Sensor Alignments

- Distance between sensors
  - P-T
  - P-T to C-Star Transmissometer
- Time of travel of water parcel through plumbing
  - P-T to C
  - P-T to DO
- Align big discrepancies in response time (i.e., DO)

## Demonstration of Misalignment Effects

Here is an artificial data set with a step change in temperature and conductivity.

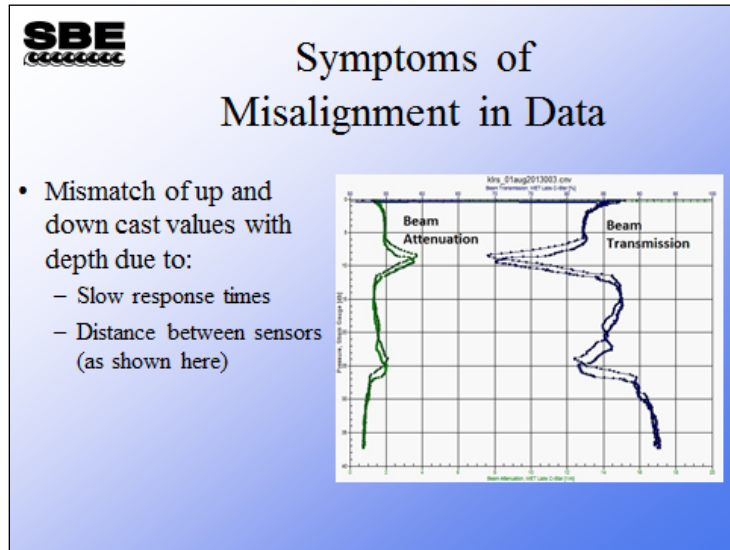

Temperature is the blue trace, conductivity is the green, and salinity is the red.

- In the top plot, T and C are perfectly matched, yielding a plot of salinity that is as expected.
- In the bottom left plot, C lags by 0.084 dbar (this is 2 scans at the *9plus* data rate, at a typical 1 m/s lowering rate). You can see that a negative spike shows up in the salinity data.
- In the bottom right plot, C leads T by 0.084 dbar, yielding a positive spike in salinity.

This behavior can be present in any CTD system built by any manufacturer. It is caused by a mismatch of T and C measurements in relation to pressure. This is not a sensor artifact; any T and C pair using any technology will produce an error in salinity if a scan contains measurements from different water parcels.

A note about the direction of the salinity spike: The direction of the salinity spike is also dependent on whether T and C are increasing or decreasing with increasing pressure. For the examples above, if T and C were decreasing rather increasing, the salinity spike would be in the opposite direction.

## Demonstration of Misalignment Effects (*continued*)

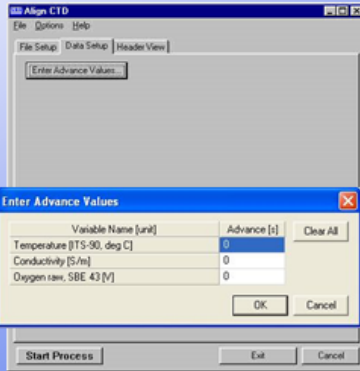

Here is data from auxiliary sensors showing misalignment.

## Removing Misalignment

**SBE** Advancing Data in Time to Remove Misalignment

- Alignment on T and C is done automatically in 11*plus* Deck Box
- Alignment can change from factory default due to changes in plumbing that increase or decrease pumping speed
- Use Align CTD module to match temperature and conductivity data streams in post processing
  - On 19*plus* and 25*plus* CTDs

Because the 911*plus* system is well characterized, an alignment of the data stream is done automatically in the 11*plus* before data is transmitted to your computer. With the TC duct in place, an alignment of 1.75 data scans (or 0.073 seconds) is done on incoming data. A linear interpolation between scans is done to implement the alignment of a non-integer number of scans.

Misalignment that differs from the nominal values can arise from plumbing changes, which can influence pumping speed. A slower pumping speed increases a water parcel's residence time in the TC plumbing, and will require a larger shift in data scans. A faster pumping speed will decrease the residence time in the TC plumbing and require a smaller alignment value.

Note that the advance values are given in seconds and are relative to the pressure channel.

## Removing Misalignment (*continued*)

### How Do I Know How Much to Advance or Slow a Data Channel?

1. Use factory defaults
  - Sea-Bird has done tests for standard configurations that provide default alignments
2. By knowing the flow rate and path distance between sensors, compute a time delay
3. By looking at your data
  - Find a spot in your data with a sharp salinity shift and/or unrealistic spiking
  - Experiment with alignment values to minimize salinity spiking

## Removing TC Misalignment: Example

This data set was collected with the secondary T and C sensors of a 911*plus* off the Faroe Islands in 1995. Note the spiky salinity data and the density inversions. These arise from two phenomena: a mismatch between temperature and conductivity samples, and ship heave. The ship heave causes water to move from around the instrument package down to the sensors during deceleration.

We will enlarge part of the plot for a closer look, and do some experimenting with sensor alignment.

A note about sensor alignment in the 911*plus*: We mentioned earlier that the 11*plus* Deck Unit performs an automatic alignment of T and C. However, in old versions of the 11*plus*, the automatic alignment was done only on the output from the primary T and C sensors; for secondary sensors we must do the alignment in post-processing.

## Removing TC Misalignment: Example (*continued*)

It is important to plot descent rate as well as density and salinity, because ship heave can cause errors in your data set that are completely different from alignment errors. To align your data, plot a small subset of the data that has sharp changes in temperature and/or conductivity. Look for spikes in the salinity and density that do not correspond to rapid descent rate decreases, which are indicative of ship heave.

## Activity: Align Data and Derive

Explanation: For this activity, we start with the .cnv file you created in *Data Conversion* that contains pressure, temperature, and conductivity, and then do some advancing on the file with *Align CTD*, trying a few advances. We then use *Derive* to calculate salinity and density from the original .cnv file and from each aligned file. We should end up with the following files, which we'll plot in *Sea Plot* to see which advance gives the best results:

- FaroeD.cnv -- Original data, with salinity and density derived
- FaroeA1D.cnv -- C advanced 1 scan (0.042 sec), with salinity and density derived
- FaroeA2D.cnv -- C advanced 2 scans (0.084 sec), with salinity and density derived
- FaroeA3D.cnv -- C advanced 3 scans (0.126 sec), with salinity and density derived

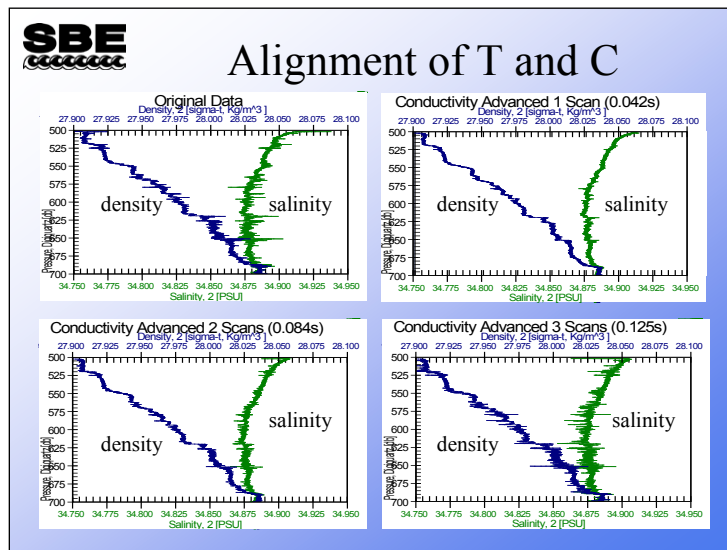

1. In SBE Data Processing, run *3. Align CTD three times*:
  - Use C:\Data\Module9\AlignC\Faroe.cnv you created in previous activity
  - Advance C relative to P 0.042, 0.084, and 0.126 seconds (1, 2, and 3 scans)
  - Name append *A1*, *A2*, and *A3*
2. In SBE Data Processing, run *6. Derive one time*, on all 4 files:
  - Use Faroe.cnv, FaroeA1.cnv, FaroeA2.cnv, and FaroeA3.cnv
  - Name append *D*
  - Calculate Salinity, Practical, 2[PSU] and Density 2 -> sigma-t, Kg/m<sup>3</sup>
3. In SBE Data Processing, run *19. Sea Plot one time* to compare results with an Overlay plot:
  - De-select *Sort input files* in Options menu, and then select input files **in order** (FaroeD.cnv, FaroeA1D.cnv, FaroeA2D.cnv, and FaroeA3D.cnv)
  - Overlay plot of P (500 to 700) vs S (34.75 to 35.00), with 0.025 offset for S
  - Now try P vs Sigma-T (27.9 to 28.1), with 0.025 offset for Sigma-T

---

If you converted 19*plus* data in the previous activity and have time, align the data in C:\Data\Module9\AlignC\SBE19plus\.

- Filter T and C to match the sensor response, using the Filter module. On the *Data Setup* tab, set Low pass filter A to a time constant of 0.5 seconds. Click *Specify Filters...* and select *none* for pressure and *Low pass filter A* for T and C.
- Use *Align CTD* to advance T against P; try whole scan *values* of 0.25, 0.5, 0.75, and 1.0 sec.
- Use *Derive* to calculate salinity and density.
- Plot results with *Sea Plot* (try P from 0 to 110, S from 36.15 to 36.6, and offset 0.05).

## Removing TC Misalignment: Example (*continued*)

This is from the Faroe data set. The data on the upper left is unaligned, raw data. The upper right has the conductivity channel advanced relative to pressure 0.42 seconds (1 scan); spiking shows considerable improvement. The plot on the lower left has conductivity advanced 0.084 seconds (2 scans) and shows some of the spikes going the other direction. The plot on the lower right has conductivity advanced 0.125 seconds (3 scans), and the spikes have reversed direction and are beginning to get longer. Note that you can align by a non-integer scan interval. In fact, the SBE 11*plus* performs an alignment for you of 1.75 scans (0.073 seconds).

## Removing TC Misalignment: Example (*continued*)

This is from the extra credit data set. The left most trace is the original unaligned data and the others, from left to right, are aligned from 1 to 4 scans. The optimal alignment value may lie between 0.25 and 0.5 seconds; it is left for the reader to experiment and find it.

## Removing Misalignment in Dissolved Oxygen

### Dissolved O<sub>2</sub> Alignment

- Sensor time constants ~ 2 - 5 seconds, depending on temperature
- Plumbing delay < 2 seconds, depending on location of sensor in flow path
- Delays add for ~ 4 seconds total
  
- Hysteresis in DO profiles is caused by plumbing delays, temperature mismatch, and sensor response time
  - Recommend corrections for deep ocean pressure > 1000 dbar

Aligning oxygen current and temperature in relation to pressure can improve hysteresis (mismatch) in dissolved oxygen profiles. The SBE 43 has a faster time constant and shows improvement in hysteresis over the Beckman- or YSI-type of sensor. Deep-ocean hysteresis corrections are advised at depths greater than 1000 dbar.

## Removing Misalignment in Dissolved Oxygen (continued)

While hysteresis is easily observed in pressure *vs.* oxygen profiles, it is also easy to confuse hydrographic phenomenon with hysteresis. The plot on the right is a shallow water plot < 1000 dbar, so is not experiencing deep-ocean hysteresis here. However, it does show hysteresis in both temperature and oxygen; the peak in oxygen has a sharp gradient in temperature associated with it. The cast was taken near the Gulf Stream, and it is likely that the ship drifted during the cast. The CTD downcast probably moved through the hydrographic feature at a different depth than the upcast. A hydrographic phenomenon should not be removed with data manipulation.

Pressure-induced hysteresis can explain differences between downcast and upcast oxygen data at depths greater than 1000 meters. For these exercises, we will not worry about deep-ocean hysteresis effects, as this was covered in Modules 7 and 8.

## Removing Misalignment in Dissolved Oxygen (continued)

Viewing hysteresis in this manner is an effective way of eliminating the confusion of hysteresis and hydrographic phenomenon.

## Activity: Align DO Data and Derive

Explanation: For this activity, we convert the raw data in *Data Conversion*, then align the data with *Align CTD*, trying a few advances. We then use *Derive* to calculate oxygen from the original .cnv file and from each aligned file. You should end up with the following files to plot in *Sea Plot* to see which advance gives the best results:

- GulfMexD.cnv                    original data, not advanced
- GulfMexA2D.cnv                dissolved oxygen advanced 2 seconds
- GulfMexA4D.cnv                dissolved oxygen advanced 4 seconds
- GulfMexA6D.cnv                dissolved oxygen advanced 6 seconds

1. In SBE Data Processing, run *Data Conversion*:
  - Use C:\Data\Module9\AlignDO\GulfMex.dat and GulfMex.con
  - Convert upcast and downcast
  - Output P, T, S, and Oxygen **raw, SBE 43 [V]**
  
2. In SBE Data Processing, run *Align CTD* **three times**:
  - Advance Oxygen Voltage SBE 43 relative to pressure 2, 4, and 6 seconds
  - Name append *A2*, *A4*, and *A6*
  
3. In SBE Data Processing, run *Derive* **one time**, on all 4 files:
  - Use GulfMex.cnv, GulfMexA2.cnv, GulfMexA4.cnv, GulfMexA6.cnv
  - Name append *D*
  - Calculate Oxygen, SBE 43 -> ml/l
  - Accept default 2.0 second window size for oxygen (on Miscellaneous tab)
  
4. In SBE Data Processing, run *Sea Plot* **one time** to compare results with an Overlay plot:
  - De-select *Sort input files* in Options menu, and then select input files **in order** (GulfMexD.cnv, GulfMexA2D.cnv, GulfMexA4D.cnv, and GulfMexA6D.cnv)
  - Overlay plot of T (17 to 28) vs Oxygen (2.5 to 8.0), with 1.0 offset for oxygen

---

If you have time, align the data in C:\Data\Module9\AlignDO\SBE19plus\ and derive oxygen, using the same procedure.

- Check your results with Sea Plot (try T from 15 to 30, Oxygen from 2.2 to 5.5, and offset 0.3).

## Removing Misalignment in Dissolved Oxygen (continued)

## Conductivity Cell Thermal Mass

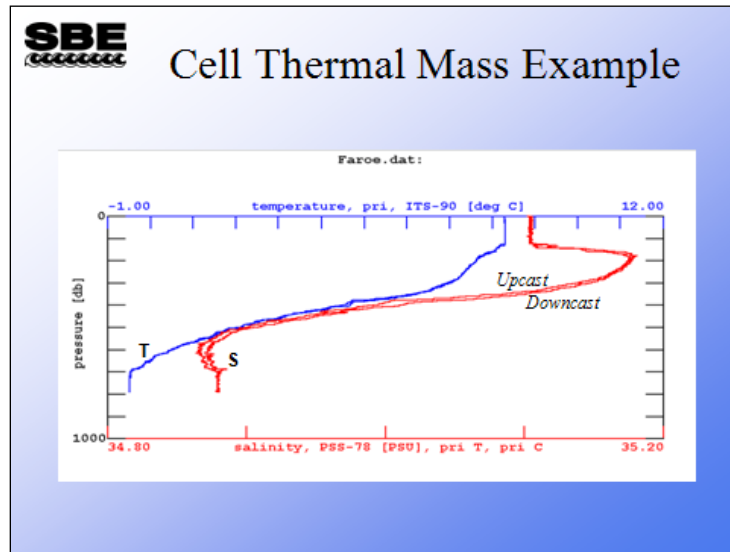

**Effect of Conductivity Cell Thermal Mass**

- Glass conductivity cell stores heat
- A warm cell warms water moving through it
  - Will read warm of correct (High)
- A cold cell cools water moving through it
  - Will read cold of correct (Low)
- Water in cell is a different temperature than the thermometer measured a moment earlier
- When salinity is computed, it will be in error

The conductivity measurement has temperature dependence. The conductivity cell itself is constructed of glass and plastic, and as such has a thermal mass. When the cell goes from warm water into cold, the water that passes through the cell is slightly warmed as it transits the cell, resulting in a conductivity measurement that is high of correct.

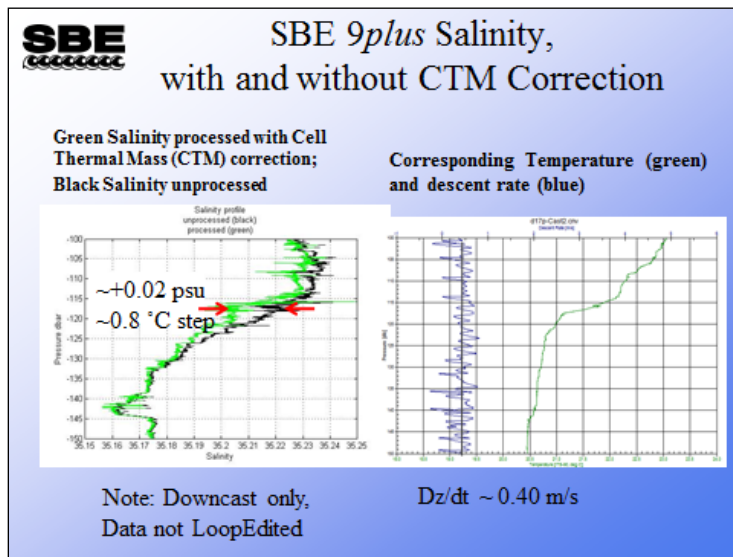

Conversely, when the cell comes up from cold water into warmer water, the water that passes through the cell is cooled slightly, resulting in a conductivity measurement that is low of correct. This heat transfer can be modeled and corrected.

## Conductivity Cell Thermal Mass (*continued*)

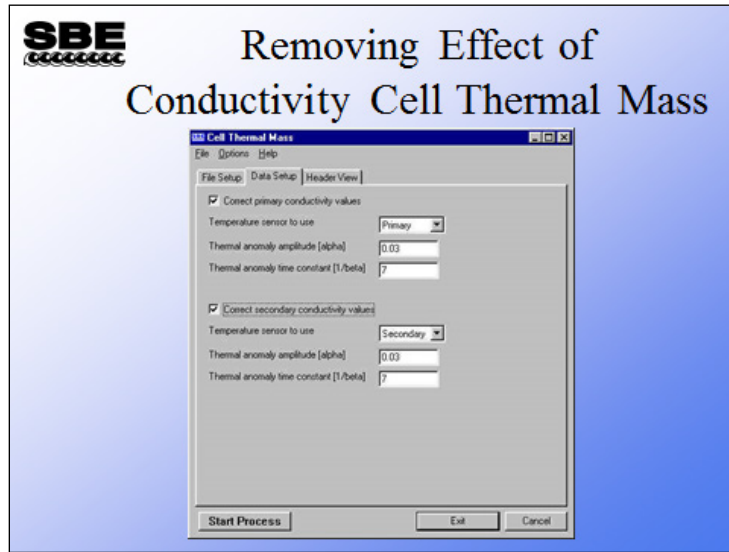

The data shown in this plot has already been aligned (using Align CTD), reducing salinity spikes associated with misalignment. We see what appears to be salinity hysteresis, but there is no temperature hysteresis. The feature that looks like salinity hysteresis is actually caused by the effect of cell thermal mass. Another way to check for cell thermal mass errors is to create a T vs S plot; the feature to look for in that plot is an open curve.

## Conductivity Cell Thermal Mass (*continued*)

## Conductivity Cell Thermal Mass (*continued*)

SBE Data Processing has a *Cell Thermal Mass* module. The thermal mass correction is made with the equation shown below, which is a function of amplitude ( $\alpha$ ) and time constant ( $1 / \beta$ ). Like many of the sensor-related phenomena we have considered, the heat transfer within the cell has a time constant.

Thermal mass correction:

$$\text{Corrected Conductivity} = C + ctm$$

Where:

$C$  = uncorrected conductivity

$$ctm = -1.0 \times b \times \text{previous } ctm + a \times \left( \frac{dc}{dT} \right) \times dT$$

$dT$  = temperature - previous temperature

$$a = 2 \times \frac{\alpha}{\text{sample interval} \times \beta + 2}$$

$$b = 1 - \left( 2 \times \frac{a}{\alpha} \right)$$

$$\frac{dc}{dT} = 0.1 \times (1 + 0.006 \times [\text{temperature} - 20])$$

## Activity: Remove Conductivity Cell Thermal Mass Effect

Explanation: For this activity, we convert the raw data in *Data Conversion*, then apply a *Cell Thermal Mass* correction. We then use *Derive* to calculate parameters from the original .cnv file and from the corrected file. You should end up with the following files to plot in *Sea Plot* to see whether the cell thermal mass correction improves the data:

- FaroeD.cnv for original data
- FaroeCD.cnv for corrected data

Note: To save time, we aren't running *Align CTD* as part of this activity, so the resulting plot of the data corrected with *Cell Thermal Mass* will still show salinity spiking. Typically, you would run *Align CTD* to eliminate salinity spikes before running *Cell Thermal Mass*.

1. In SBE Data Processing, run *Data Conversion*:
  - Use C:\Data\Module9\CellTM\Faroe.dat and .con
  - Convert upcast and downcast
  - Output
    - Time, Elapsed -> seconds
    - Pressure, Digiquartz -> db
    - Temperature -> ITS-90 -> deg C
    - Conductivity -> S/m
2. In SBE Data Processing, run *Cell Thermal Mass*:
  - Use defaults
  - Name append C
3. In SBE Data Processing, run *Derive* **one time**, on 2 files:
  - Use Faroe.cnv and FaroeC.cnv
  - Name append D
  - Calculate Salinity
4. In SBE Data Processing, run *Sea Plot* **one time** to compare results with an Overlay plot:
  - De-select *Sort input files* in Options menu, and then select input files **in order** (FaroeD.cnv and FaroeCD.cnv)
  - Overlay plot of Pressure (500 to 700) on y-axis; Salinity (34.85 to 34.95) and Temperature (-0.5 to 3.5) on x-axes. Use 0.05 offset for salinity, 1.0 offset for temperature.

**Activity (continued)**

Note that the *corrected* curve still shows what looks like salinity hysteresis, so the correction could perhaps use some refinement. You could repeat the process for other values of alpha and beta, to find the best result.

## Data Artifacts Induced by Ship Heave

**SBE**  How to Remove Ship Heave Effects on CTD Data

- Data errors caused by CTD profiling reversals are flagged by scan line
- We can choose to omit these “flagged” data from averaging and plots

## Data Artifacts Induced by Ship Heave (*continued*)

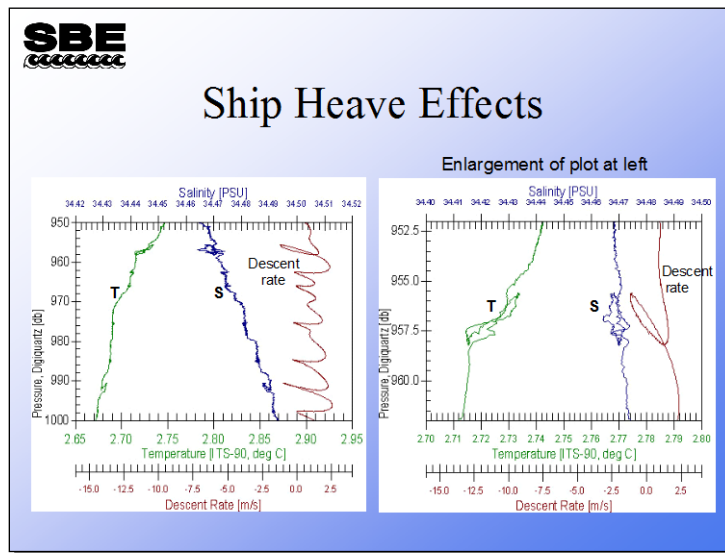

Ship heave is the rocking motion of the ship. Most CTD deployments are made with a small boom or an A-frame that leans out from the ship, giving some distance between the sea cable and the side of the ship. Ship rocking has the effect of pulling up on the sea cable when the ship rocks in one direction and slackening the sea cable when it rocks in the other. This heaving action causes the underwater package to decelerate when the sea cable is pulled up and accelerate when it goes slack. Most instrument packages have sufficient cross section that the deceleration effect is more pronounced than the acceleration.

As the instrument decelerates, water that is entrained within the package can continue downward past the sensors. This water is of different temperature and conductivity than the water at the bottom of the package, and it causes a sampling error.

Further, in cases of radical ship heave, the instrument package can have a trajectory through the water column that describes loops. It goes without saying that this sort of behavior causes sampling errors.

## Data Artifacts Induced by Ship Heave (*continued*)

These two plots show the effect of ship heave. Both plots show descent rate in brown. The plot on the left shows that each time the descent rate drops, the temperature and salinity traces are disturbed. The plot on the right is an enlargement of a portion of the left plot, showing the loop trajectory that was mentioned previously.

## Data Artifacts Induced by Ship Heave (*continued*)

## Data Artifacts Induced by Ship Heave (*continued*)

### Removing Package-Induced Data Artifacts

- Data errors introduced this way must be flagged in the data file or deleted
  - There is no *fix*
- *Loop Edit* flags scans of data that experienced reversals or loops caused by ship heave
- *Wild Edit* removes data that fall outside of user-specified limits

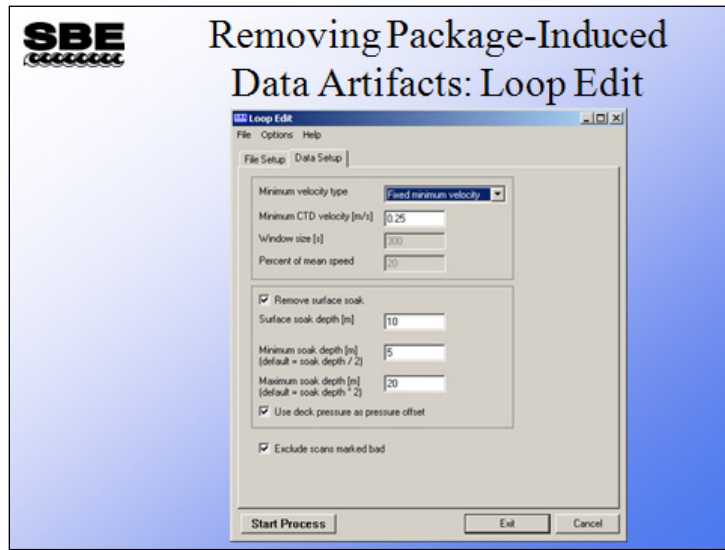

The error caused by ship heave comes from the instrument package disturbing the water that it is trying to sample. Because of this, there is no numerical solution for the problem. SBE Data Processing has two editing modules that remove the offending data. As winch technology improves, we can expect to see vessels equipped with motion compensation capability, which will greatly reduce this problem. Until that is available, you may want to profile a bit more quickly to reduce the effect of ship heave in rough water.

*Loop Edit* marks data collected when the CTD loops through the water or decelerates sharply.

*Wild Edit* marks data that falls outside of user-specified limits, given as standard deviations of a window of data; this *bad* data may be caused by a telemetry problem or perhaps a critter or piece of debris going through the conductivity cell.

Data that is marked by these modules can be omitted in subsequent processing steps.

## Data Artifacts Induced by Ship Heave (*continued*)

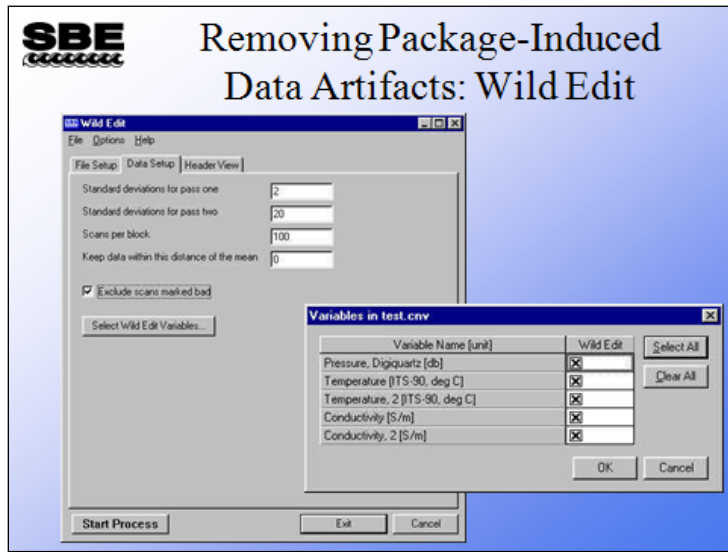

For Loop Edit:

- The default minimum velocity is 0.25 m/sec, which is 25% of the typical nominal descent rate of 1 m/sec. Typically, you should use the *Percent of mean speed* algorithm if the cast had a variable descent rate; otherwise, use *Fixed minimum velocity*.
- If *Remove surface soak* is selected, the scans related to the surface soak are also marked. See the SBE Data Processing manual or Help files for details on setting up the soak depth parameters. The *Use deck pressure as pressure offset* selection relates only to the marking of surface soak data, and has no effect on the pressure data in the file.

## Data Artifacts Induced by Ship Heave (*continued*)

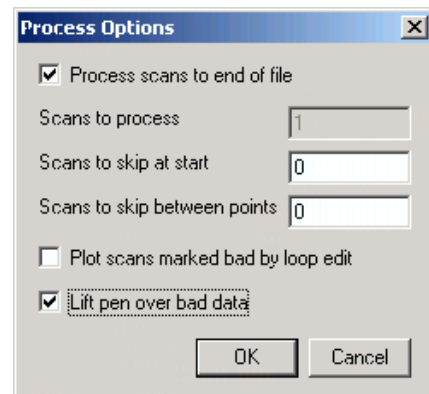

## Activity: Remove Loops

Explanation: For this activity, we convert the raw data in *Data Conversion*, then *Filter* the data, and look for loops with *Loop Edit* using two different methods. You should end up with the following files to plot in *Sea Plot*:

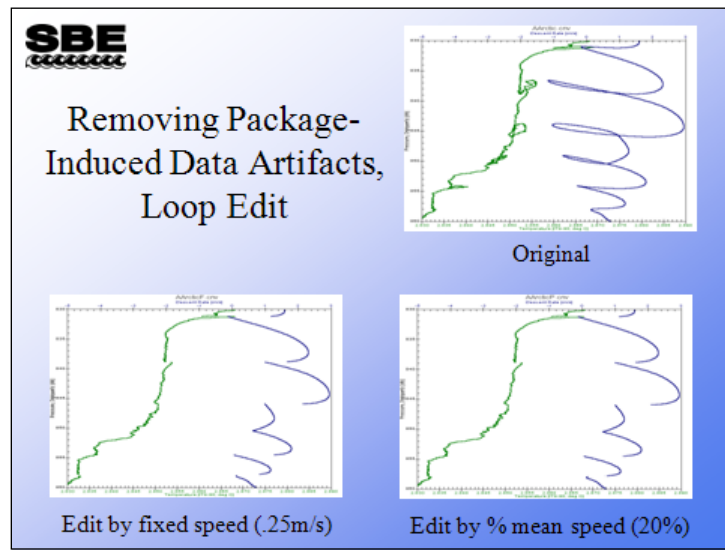

- AArctic.cnv original file, not filtered or corrected for loops
- AArcticFilterP.cnv corrected for loops using percent of mean speed
- AArcticFilterF.cnv corrected for loops using fixed velocity

1. In SBE Data Processing, run *Data Conversion*:
  - Use C:\Data\Module9\Loop\AArctic.dat and .con
  - Convert downcast only
  - Output
    - Time, Elapsed -> seconds
    - Pressure, Digiquartz -> db
    - Temperature -> ITS-90 -> deg C
    - Descent rate
2. In SBE Data Processing, run *Filter*:
  - Filter pressure with time constant 0.15 seconds
  - Name append *Filter*
3. In SBE Data Processing, run *Loop Edit* **two times**:
  - Use AArcticFilter.cnv as input file each time
  - **Uncheck** *Remove surface soak* and *Exclude scans marked bad*.
  - Run with name append *P*, percent mean speed, 300 second window, 20% mean speed
  - Run with name append *F*, fixed minimum velocity, 0.25 m/sec
4. Open **three copies** of SBE Data Processing; run *Sea Plot* **in each copy** to compare results:
  - Plot AArcticFilter.cnv in one copy, AArcticFilterP.cnv in the second copy, and AArcticFilterF.cnv in the third copy.
  - On Plot Setup tab, click *Process options* button, and check *Lift pen over bad data*
  - Y axis Pressure (830 to 860 db), X axis1 Temperature (2.83 to 2.89 deg C), X axis2 Descent rate (-5 to 3 m/sec)

Note: An alternate way to do this exercise is to use an overlay plot to plot all three files on one plot, but you may decide that the plot is too *busy* to be useful.

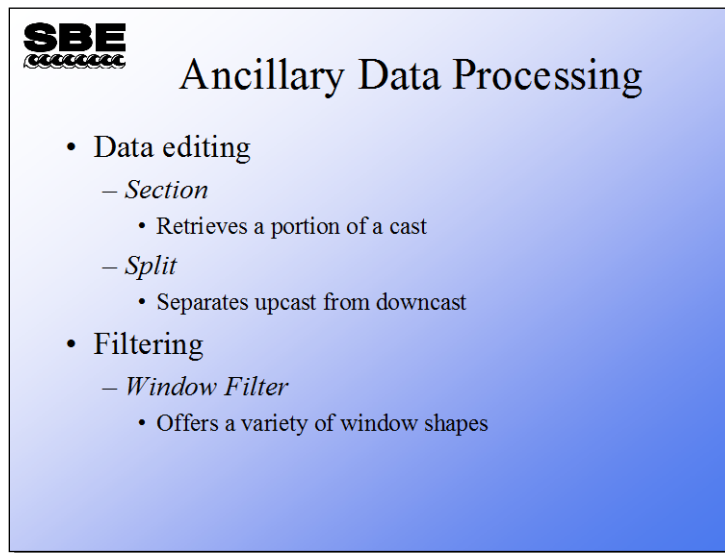

## Data Artifacts Induced by Ship Heave (*continued*)

Here is the example of loopy data that we showed earlier. The bottom two plots have been edited by the two means available. Both plots show very similar results. The bottom left plot is made by editing out data that drop below a fixed speed, in this case 0.25m/s. The bottom right plot is made by editing data that drops below 20% of the mean speed calculated over a 5-minute (300-second) window; this method gives you a bit more flexibility.

## Ancillary Data Processing

A blue gradient rectangular box containing the SBE logo (with a stylized wave below the letters) in the top left corner. To the right of the logo is the title "Ancillary Data Processing". Below the title is a bulleted list of processing options: "Data editing" (with sub-items "Section" and "Split"), and "Filtering" (with sub-item "Window Filter").

**SBE**  
*ccccccc*

### Ancillary Data Processing

- Data editing
  - *Section*
    - Retrieves a portion of a cast
  - *Split*
    - Separates upcast from downcast
- Filtering
  - *Window Filter*
    - Offers a variety of window shapes

In addition to the data processing modules and procedures we have talked about, there are other modules available.

- Clip out part of your data with *Section*.
- Separate your data into upcasts and downcasts with *Split*.
- Use various shaped windows (boxcar, cosine, Gaussian, median, or triangle) to filter your data with *Window Filter*. The median filter is particularly good at preserving sharp steps in the data while rejecting noise.

## Bin Averaging

### Bin Averaging

- Reduces size of a data set by statistically estimating data values at even intervals (e.g., every meter or 10 meters)
- Can work in depth (meters), pressure (decibars), time, or by scan
- Can bin average upcast, downcast, or both
  - If bin averaging upcast and downcast, keeps upcast bins and downcast bins separate
- The surface bin is treated separately

Bin averaging is a means of reducing your data set to a more tractable, and perhaps a more meaningful, size. The Bin Average module makes a statistical estimate of data values at a user-prescribed interval based on the surrounding data. You can bin data on the even meter or 10 meters. You can bin data with a bin size that represents the resolution of your instrument. For time series measurements, you can bin on time interval.

## Bin Averaging: Processing Protocol

**SBE**  
*acoustic*

### Bin Averaging Protocol: Pressure Interpolated

- A linear estimate of variable  $X_i$  at bin pressure  $P_i$

$$X_i = \frac{(X_c - X_p) * (P_i - P_p)}{(P_c - P_p)} + X_p$$

$P_p$  = average pressure of previous bin     $X_p$  = average value of variable in previous bin  
 $P_c$  = average pressure of current bin     $X_c$  = average value of variable in current bin  
 $P_i$  = center value for pressure in current bin

\_\_\_\_\_ surface = 0 db  
 Minimum first bin =  
 bin size - (bin size/2) = 5 db  
 First bin    Bin size=10 db  
 Sum and average all data within bin,  
 then interpolate to calculate value of  
 variable at center of bin  
 \_\_\_\_\_ Center (target) first bin =  
 bin size = 10 db  
 Maximum first bin =  
 bin size + (bin size/2) = 15 db

An estimate of each variable is made using the average value of that variable and pressure in the previous bin, and the average values of the variable and pressure in the current bin. Bin averaging with interpolation provides output data at regular intervals (for example, 10 meters, 20 meters, etc.).

## Bin Averaging: Processing Protocol (*continued*)

### Bin Average Protocol: Pressure, Not Interpolated

- Data within a bin is averaged by summing and dividing by number of points within bin

\_\_\_\_\_ surface = 0 db

\_\_\_\_\_ Minimum first bin =  
bin size - (bin size/2) = 5 db

↑ First bin  
Bin size=10 db  
Sum and average  
all data within bin

\_\_\_\_\_ Center (target) first bin =  
bin size = 10 db

\_\_\_\_\_ Maximum first bin =  
bin size + (bin size/2) = 15 db

This protocol averages all the data within the bin, producing uneven bin pressures or depths. For example, if you are binning on 10-meter intervals, the first bin start is 5 meters and the end is 15 meters. All data within this window is averaged, producing a bin depth of approximately 10 meters (e.g., 10.123 meters).

Note that some data bases require data on even intervals (10 m, 20 m, etc.), so averaging without interpolation will not meet the needs of those data bases; use bin averaging with interpolation instead.

## Bin Averaging: Surface Bin

**SBE**  
*Micrologger*

### The Surface Bin

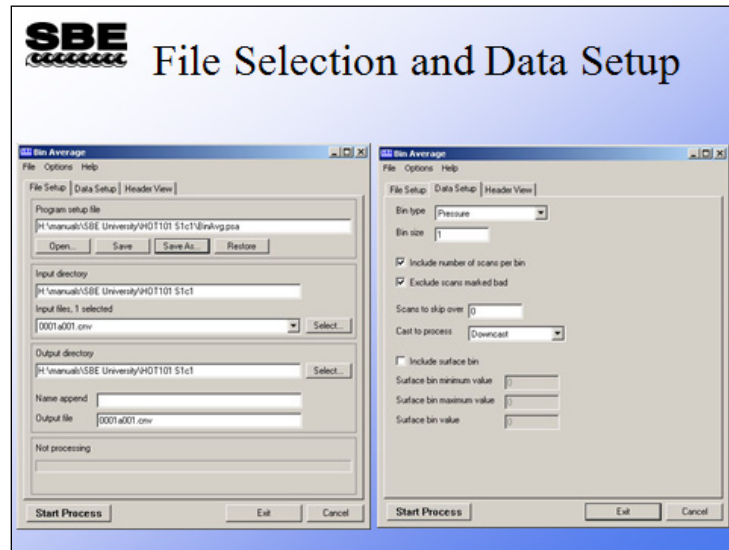

- Surface bin constrained by user data entries: minimum, maximum, and assigned pressure or depth

<p>Surface bin Bin size=3 db</p>	<p>minimum surface bin = 0 db target surface bin = 0 db</p> <p>maximum surface bin = 3 db</p>
<p>First bin Bin size=10 db</p>	<p>Minimum first bin = bin size - (bin size/2) = 5 db</p> <p>Center (target) first bin = bin size=10 db</p> <p>Maximum first bin = bin size + (bin size/2) = 15 db</p>

The surface bin is handled differently because the previous bin would be up in the air. The surface bin is assigned a beginning pressure or depth, an ending pressure or depth, and a target pressure or depth.

## Bin Averaging: File Selection and Data Setup

The Data Setup tab allows your choice of pressure, depth, time, or scan bins. You can include the number of scans per bin in the output file, which is useful for evaluating data from instruments with a low sample rate. Bins with 1 sample in them are not very accurate statistically.

You can skip data that you acquired while checking out your instrument before the cast started. Similar to previous processing, you can process the upcast, downcast, or both.

Earlier in this module, we discussed techniques for removing suspect data. These data are marked in the data set as *bad scans*. When setting up *Bin Averaging*, you may exclude scans marked bad by previous processing steps.

As mentioned earlier, the surface bin is handled separately. Note that in our example the surface bin is not included, because we are binning on a 1-meter interval. If you bin on a small interval, it is very difficult to calculate a surface bin. For example, with 1-meter bins, a surface bin would run from 0 to 0.5 meters with value 0.25 meters; depending on the profiling and sampling speeds, there would be few samples within that depth. The surface bin is useful for a coarser bin size. For example, with 10-meter bins, the first bin starts at 5 meters and runs to 15 meters. You can succeed in calculating a surface bin that runs from 0 to 5 meters with value 2.5 meters.

## Bin Averaging: Output Data

```
SBE  
Bin Average: Output Data  
  
# binavg_bintype = meters  
# binavg_binsize = 1  
# binavg_excl_bad_scans = yes  
# binavg_skipover = 0  
# binavg_surface_bin = no, min = 0.000, max = 5.000, value = 2.500  
# file_type = ascii  
*END*  
1.000 24.9124 35.2455 100 0.0000e+00  
2.000 24.9582 35.2463 90 0.0000e+00  
3.000 25.0029 35.2477 36 0.0000e+00
```

Bin Average processes all variables in the input .cnv file, and inserts a column before the error flag column if you selected *include number of scans per bin*.

The output columns for the example bin averaged data above are:

- Bin depth
- Temperature (°C)
- Salinity (PSU)
- Number of scans per bin (only if *Include number of scans per bin* was selected)
- Error flag

## Activity

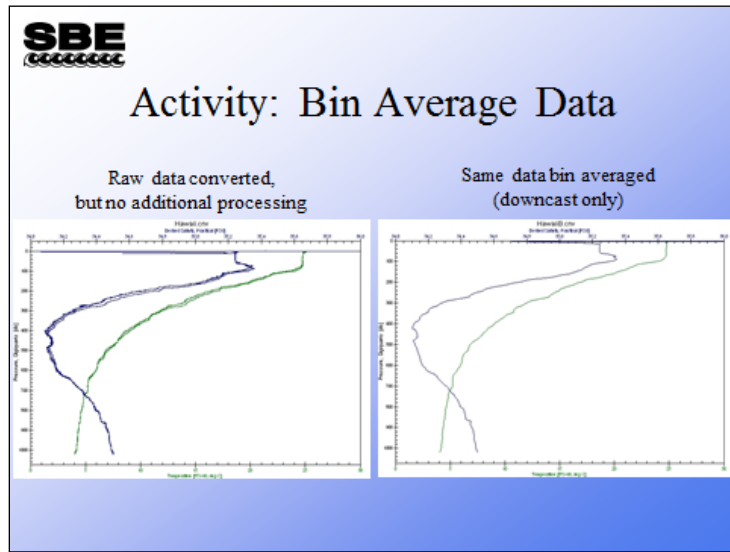

1. In SBE Data Processing, run *Bin Average* to create 5 decibar bins:
  - Use C:\Data\Module9\BinAverage\Hawaii.cnv
  - Name append *B*
  - Data Setup
    - Choose Pressure for *Bin Type*
    - Enter *Bin size* of 5
    - Check *Include number of scans per bin*
    - Check *Exclude scans marked bad*
    - Skip over 0 scans*
    - Process the downcast*
    - Include the Surface bin*
      - Surface bin minimum value 0*
      - Surface bin maximum value 5*
      - Surface bin value 2.5*
2. Open HawaiiB.cnv in Notepad or Wordpad and take a look at the header and data.
3. If you have time, plot the full data set and the bin averaged data set:
  - Open 2 copies of SBE Data Processing
  - Plot Hawaii.cnv in one, and HawaiiB.cnv in the other

---

If you have time, bin average 19*plus* data (C:\Data\Module9\BinAverage\Miami.cnv):

- 1 decibar bins
- Include surface bin
  - surface bin minimum value 0*
  - surface maximum value 1*
  - surface bin value 0.5*

## Activity (*continued*)

The plot on the left is one we looked at in Module 3, for data that had been converted using Data Conversion, but not yet *processed* using the advanced processing techniques we reviewed today. That plot shows both the upcast and downcast.

The plot on the right is for the same data, but bin averaged. Notice that many of the features are smoothed out when looking at Bin Averaged data. If you will be using any of the advanced processing techniques we discussed today, **do not Bin Average data before you do the advanced processing.**

## Data Processing Tips

Data Processing Notes

- Best data is collected at highest rate instrument is capable of
- Data should not be *reprocessed*
- Calculation of derived parameters and bin averaging should be done last

A final note: Collect your data at the highest speed you can. Do not reprocess data; if you advance data channels and bin average them or derive other parameters from them, do not advance them again. Derivation of salinity, density, etc. and bin averaging should be the last step after you process and edit your data. The decision to *Derive* and then *Bin Average* or to *Bin Average* and then *Derive* is yours. If you *Bin Average* first you will be *Deriving* from statistical estimates made from your data. If you *Derive* and then *Bin Average*, you will be creating statistical estimates of your derived quantities.

## Data Processing Steps: SBE 9*plus* / 11*plus*

**SBE** Processing Steps: SBE 9-11*plus* Data

- **Data Conversion**
  - Output up/downcasts of all parameters
  - Only process independent parameters (T,C,P, OXVOLTS, Modulo Errors, etc.)
  - Output converted variables (salinity, DO concentration) if comparing to water samples
- **Align CTD**
  - SBE 11*plus* Deck Box usually advances primary C +0.073 sec, sometimes secondary C
  - Align Dissolved Oxygen (DO) (2-3 sec) and other sensor data accordingly in post processing
- **Filter**
  - Only if continuous time series and no Pressure outliers
  - Filter Pressure at +0.15 sec
- **Loop Edit**
  - Only if ship heave a problem (if you see loops or high standard deviations in descent rate)
  - Use minimum fall speed from CTD descent rate plots
- **Cell Thermal Mass**
  - ALWAYS apply this correction in Saltwater applications on moving platforms (not moored)
  - Do NOT apply this correction in Freshwater applications
  - Parameters: Alpha = 0.03 and Tau = 7 sec
- **Derive**
  - Compute Salinity, DO concentration, and other dependent variables (Density, Specific Conductance, etc.)
- **Bin Average**
  - Average data into depth, time, or pressure bins AFTER DERIVING computed variables

This is an ordered list of the steps in processing of CTD data gathered with the 911*plus*.

Notes:

1. Enable the oxygen deep-water hysteresis correction on the Miscellaneous tab in Data Conversion.
2. Data is bin averaged after the major derived quantities are computed. Salinity, DO density, etc., are functions of T, C, and P; these are calculated on the final values of T, C, and P rather than the intermediate values.

## Data Processing Steps: SBE 19*plus* or 19*plus* V2

Processing Steps: SBE 19*plus* Data

- **Data Conversion**
  - Output up /downcasts of all parameters.
  - Only process on independent parameters (T,C,P, OXVOLTS, etc.)
  - Output converted variables (salinity, DO concentration) if comparing to water samples
- **Align CTD**
  - Advance Temperature +0.5 sec, Conductivity 0-0.1 sec, and Dissolved Oxygen Voltage 3-5 sec
- **Filter**
  - Only if continuous time series and no outliers
  - Filter Pressure at +1.0 sec, and Temperature and Conductivity at +0.5 sec
- **Loop Edit**
  - Only if ship heave a problem (if you see loops or high standard deviations in descent rate)
  - Use minimum fall speed from CTD descent rate plots
- **Cell Thermal Mass**
  - ALWAYS apply this correction in Saltwater applications on moving platforms (not moored)
  - Do NOT apply this correction in Freshwater applications
  - Parameters: Alpha = 0.04 and Tau = 8 sec
- **Derive**
  - Compute Salinity, DO concentration, and other dependent variables (Density, Specific Conductance, etc.)
- **Bin Average**
  - Average data into depth, time, or pressure bins AFTER DERIVING computed variables

For acquiring data:

- Use Seasave if acquiring real-time data.
- Use one of the terminal programs if uploading data from the instrument memory:  
SeatermV2 for the 19*plus* V2, Seaterm for the 19*plus*.

## Data Processing Steps: SBE 25plus

Processing Steps: SBE 25plus Data

- **Data Conversion**
  - Output up /downcasts of all parameters.
  - Only process on independent parameters (T,C,P, OXVOLTS, etc.)
  - Output converted variables (salinity, DO concentration) if comparing to water samples
- **Align CTD**
  - Advance Conductivity+0.1 sec and Dissolved Oxygen (DO) Voltage 3-5 sec
- **Filter**
  - Only if continuous time series and no P outliers
  - Filter Pressure at +0.5 sec
- **Loop Edit**
  - Only if ship heave a problem (if you see loops or high standard deviations in descent rate)
  - Use minimum fall speed from CTD descent rate plots
- **Cell Thermal Mass**
  - ALWAYS apply this correction in Saltwater applications on moving platforms (not moored)
  - Do NOT apply this correction in Freshwater applications
  - Parameters: Alpha = 0.04 and Tau = 8 sec
- **Derive**
  - Compute Salinity, DO concentration, and other dependent variables (Density, Specific Conductance, etc.)
- **Bin Average**
  - Average data into depth, time, or pressure bins AFTER DERIVING computed variables

For acquiring data:

- Use Seasave if acquiring real-time data.
- Use SeatermV2 terminal program if uploading data from the instrument memory

## Data Processing of Large Numbers of Files

### Batch Processing

- Batch processing frees you from processing each cast individually
- Batch processing is done from a command line prompt
  - Win2000/XP run “command” from *Start -> Run* dialog gives you an MSDOS window
  - Win95/98 use an MSDOS window
  - Run SBEBatch directly from *Start -> Run* dialog
- Format for sbebatch is:
  - sbebatch filename parameters

For processing large sets of cast data, batch mode processing automates the job. You can use the windows scripting host or a program provided with SBE Data Processing, SBEBatch.exe. Your batch file can take advantage of command line parameters and wild card characters.

You can run SBEBatch from a DOS window or from the Windows Run dialog (Start -> Run). In all the examples we’ll use today (and the examples in the SBE Data Processing manual), we’re assuming you are running from the Windows Run dialog box.

## Data Processing of Large Numbers of Files (*continued*)

### Batch Processing

- Batch processing uses an application that runs other applications (*i.e.*, data processing applications)
- You may use the Windows Scripting Host or an application Sea-Bird provides, *SBEBatch*
- The applications that the batch processor runs are listed in a text file that you make with a text editor like Notepad
  - A list of applications are shown in your notes
- SBEBatch reads each line of the text file and runs each application in turn

Applications:

Module	Process Name
Align CTD	Alignctd
ASCII In	Asciin
ASCII Out	Asciout
Bin Average	Binavg
Bottle Summary	Bottlesum
Buoyancy	Buoyancy
Cell Thermal Mass	Celltm
Data Conversion	Datcnv
Derive	Derive
Filter	Filter
Loop Edit	Loopedit
Mark Scan	Markscan
Sea Plot	Seaplot
Section	Section
Split	Split
Strip	Strip
Translate	Trans
Wild Edit	Wildedit
Window Filter	Wfilter

## Data Processing of Large Numbers of Files (*continued*)

**SBE**  
*SCIENTIFIC BUSINESS ELECTRONICS*

### Batch Processing

- Each line of your batch file contains
  - Name of the application
  - Name of the files to operate on
  - Any additional parameters needed to do the job
- Parameters are denoted by the '/' character and an identifier; a table of parameters is shown in your notes
- For example, a batch processing file that runs *Data Conversion* on 1 data file looks like:  
     DatCnv /iC:\MyData.dat /cC:\MyCTD.con
  - Input file is C:\MyData.dat, designated by /i
  - Configuration file is C:\MyCTD.con, designated by /c
  - This will cause *Data Conversion* to use last .psa file, substituting .dat and .con file from batch file for files specified in .psa file, and create MyData.cnv

A list of the most commonly used parameters follows; see the SBE Data Processing manual for a complete list:

Parameter	Description
/cString	Use <i>String</i> as instrument <b>configuration (.con or .xmlcon) file</b> . <i>String</i> must include full path and file name. Note: If using /cString, must also specify input file name (using /iString).
/iString	Use <i>String</i> as <b>input file name</b> . <i>String</i> must include full path and file name. This parameter supports standard wildcard expansion: <ul style="list-style-type: none"> <li>• ? matches any single character in specified position within file name or extension</li> <li>• * matches any set of characters starting at specified position within file name or extension and continuing until end of file name or extension or another specified character</li> </ul>
/oString	Use <i>String</i> as <b>output directory</b> (not including file name).
/fString	Use <i>String</i> as <b>output file name</b> (not including directory).
/aString	<b>Append <i>String</i> to output file name</b> (before extension).
/pString	Use <i>String</i> as <b>Program Setup (.psa) file</b> . <i>String</i> must include full path and file name.
/xModule: String	Use <i>String</i> to define an additional parameter to pass to Module. Not all modules have x parameters; see module descriptions for details. If specifying multiple x parameters, enclose in double quotes and separate with a space. <i>Example:</i> Run Data Conversion, telling it to skip first 1000 scans: /xdatcnv:skip1000
#m	Minimize SBE Data Processing window while processing data, allowing you to do other work on computer.

**If specifying multiple parameters, insert a space between each parameter in the list.**

## Data Processing of Large Numbers of Files (*continued*)

### Batch Processing Script

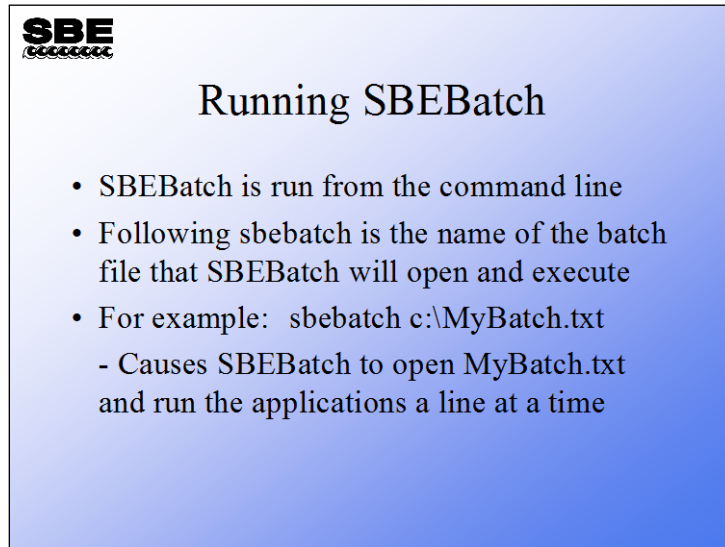

- To process all the files in a folder use a wildcard: the '\*' character
- For example, a batch processing file that runs Data Conversion on all data files in a folder looks like:

```
datenv /iC:\Data\*.dat /cC:\Data\MyCTD.con
```

- Input files are all *.dat* files in C:\Data\

- Configuration file is C:\Data\MyCTD.con

## Data Processing of Large Numbers of Files (*continued*)

**SBE**  
*Scientific Batch Execution*

### Running SBEBatch

- SBEBatch is run from the command line
- Following sbebatch is the name of the batch file that SBEBatch will open and execute
- For example: `sbebatch c:\MyBatch.txt`  
 - Causes SBEBatch to open MyBatch.txt and run the applications a line at a time

Here's an example of how to use batch processing to run Data Conversion and Derive to process all the files in C:\Data:

1. Run Data Conversion, entering the desired choices in the File Setup and Data Setup dialog boxes. Upon completing setup, press Save or Save As on the File Setup tab. The configuration is stored in the .psa file. Repeat for Derive.
2. Create a batch file named batch.txt in C:\Data, which contains the following lines:  
 @Lines starting with @ are comment lines, and have no effect on the result  
 @Use these to document what you are doing in the batch file  
 @Processing data from February 2006 Cruise  
`datcnv /iC:\Data\*.dat /cC:\Data\MyCTD.con`  
`derive /iC:\Data\*.cnv /cC:\Data\MyCTD.con`
3. Select Run in the Windows Start menu. The Run Dialog box appears. Type in the batch processing program name and the .txt file name:  
`sbebatch c:\Data\batch.txt`

The results:

1. Data Conversion uses its last .psa file, substituting the .con file from the batch file for the .con file specified in the .psa file, and processes **all** .dat files in C:\Data, creating a .cnv file from each .dat file.
2. Derive uses its last .psa file, substituting the .con file from the batch file for the .con file specified in the .psa file, and processes **all** .cnv files in C:\Data (which were just created by Data Conversion), creating a .cnv file from each .cnv file.

## Data Processing of Large Numbers of Files (*continued*)

### Batch Processing Script

- Remember that the format for running SBEbatch is:  
sbatch filename *parameters*
- You can operate on files in different folders with the same batch file by using command line *parameters*
- These are entered after the batch file name and are denoted by the '%' character and a number
  - The first command line parameter is %1,  
the second is %2, etc.
- Your batch file must have entries that use the '%' parameters

## Data Processing of Large Numbers of Files (*continued*)

### Batch Processing Script

- For example, a batch file that has this line in C:\MyBatch.txt  
`DatCnv /i%1\*.dat /c%1\MyCTD.con`  
 Executed with this command line  
`SBEBatch C:\MyBatch.txt C:\Data`  
 (C:\Data is the %1 parameter)  
 Will cause Data Conversion to be run like this:  
`DatCnv /iC:\Data\*.dat /cC:\Data\MyCTD.con`  
 All the .dat files in C:\Data will be converted
- For the same batch file, if the command line is  
`SBEBatch C:\MyBatch.txt C:\NewData`  
 All the .dat files in C:\NewData will be converted

Now let's add a bit more flexibility to the process. Here's an example of how to use batch processing to run Data Conversion and Derive to process all the data files in C:\Data\Leg1, C:\Data\Leg2, and C:\Data\Leg3:

1. Run Data Conversion, entering the desired choices in the File Setup and Data Setup dialog boxes. Select *Match instrument configuration to input file* on the File Setup tab. Upon completing setup, press Save or Save As on the File Setup tab. The configuration is stored in the .psa file.  
Repeat for Derive.
2. Create a batch file named batch.txt in C:\Data, which contains the following lines:  
`@Processing data from 3 legs of February 2006 Cruise`  
`datcnv /i%1\*.dat`  
`derive /i%1\*.cnv`
3. Select Run in the Windows Start menu. The Run Dialog box appears.  
Type in the batch processing program name, the .txt file name, and the %1 parameter:  
`sbebatch C:\Data\batch.txt C:\Data\Leg1`  
 Repeat for the files in Leg2 and Leg3:  
`sbebatch C:\Data\batch.txt C:\Data\Leg2`  
`sbebatch C:\Data\batch.txt C:\Data\Leg3`

The results:

1. Data Conversion uses its last .psa file, substituting the matching .con file for the .con file specified in the .psa file, and processes **all** .dat files in C:\Data\Leg1, creating a .cnv file from each .dat file.
2. Derive uses its last .psa file, substituting the matching .con file for the .con file specified in the .psa file, and processes **all** .cnv files in C:\Data\Leg1 (which were just created by Data Conversion), creating a .cnv file from each .cnv file.
3. Steps 1 and 2 are repeated for the files in C:\Data\Leg2 and C:\Data\Leg3.

## Activity

Explanation: We will prepare Data Conversion and Bin Average to operate with your batch file, by setting up the desired output parameters, bin size, etc. The saved .psa files contain all the information on the setup. And then we will create a batch processing script to process a large number of files in the same way.

1. In SBE Data Processing, run *Data Conversion*:
  - Use C:\Data\Module9\Batch\Puget00.hex
  - Downcast only
  - Calculate Pressure, Temperature, and Salinity
  - Save .psa file as C:\Data\Module9\Batch\DatCnv.psa
2. In SBE Data Processing, run *Bin Average* to create 1 decibar bins:
  - Use C:\Data\Module9\Batch\Puget00.cnv
  - Name append *B*
  - Data Setup
    - Choose Pressure for *Bin Type*
    - Enter *Bin size* of 1
    - Process* the downcast
    - Make other selections as desired
3. Delete Puget00.cnv and Puget00B.cnv.
  - Delete these output files from Data Conversion and Bin Average because they will be recreated by the batch processing script.
4. Create a batch processing script to process **all** files in C:\Data\Module9\Batch (Puget00.hex, Puget01.hex, etc.):
  - Use Notepad to write your batch file, using a %1 parameter for the file locations.
  - Save your batch file as C:\Data\Module9\Batch\MyBatch.txt
5. Launch a command line session: Click Start > Run.
6. Run your batch file with the command line:  
**Sbbatch C:\Data\Module9\Batch\MyBatch.txt C:\Data\Module9\Batch**
7. Check to see that you were successful with Notepad
